Overview

- Computational models in systems biology
- Model checking
- Multiscale spatio-temporal model checking
- Multiscale spatio-temporal *meta* model checking
- Implementation
- Case study: Acute inflammation of gut and lung
- Conclusions

Model Checking

david.gilbert@brunel.ac.uk

"Formally check whether
a model of a biochemical system does what we want"

Components:

model

- the current description of a biochemical system of interest

property

- a property which we think the system should have

model checker

- a program to test whether the model has the property

To formally express time properties we use a temporal logic

david.gilbert@brunel.ac.uk

- "*I am hungry*."
- "*I am always hungry*", "*I will eventually be hungry*",
- *"I will be hungry until I eat something*".

Linear time logics restricted to single time line.

Branching logics can reason about multiple time lines.
"*There is a possibility that I will stay hungry forever*."
"*There is a possibility that eventually I am no longer hungry*."

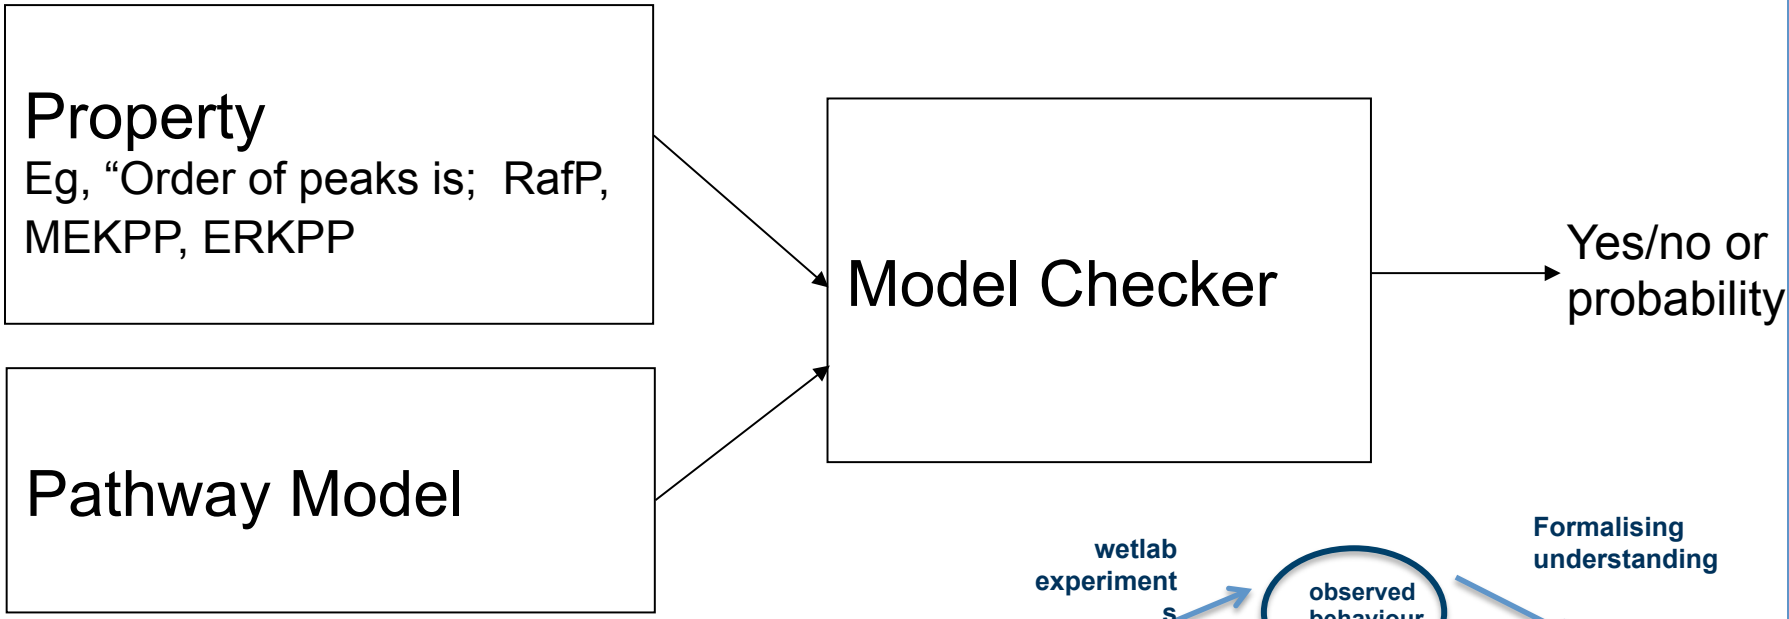
Various logics :

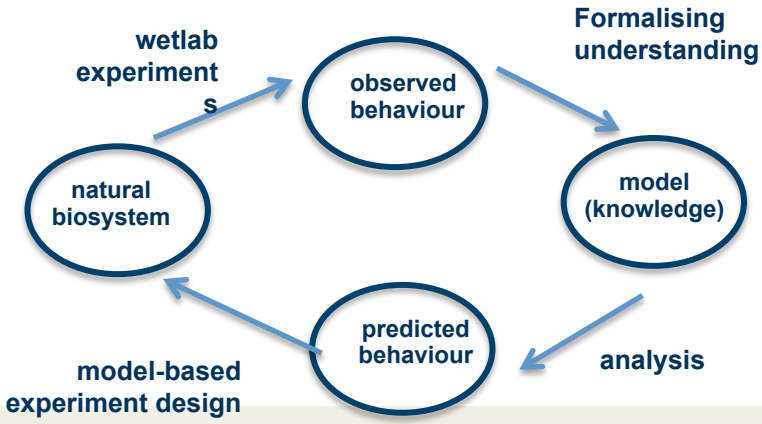
- Computational Tree Logic (CTL)
- Continuous Stochastic Logic (CSL)
- Linear-time Temporal Logic (LTL)

each with different expressivity.

Model Checking Biochemical Pathways

david.gilbert@brunel.ac.uk





Properties…

david.gilbert@brunel.ac.uk

Examples:

- After 100 seconds the concentration of Protein1 is stable
- Protein1 peaks and falls
- Protein1 peaks and stays constant
- Protein1 peaks before Protein2
- Protein1 oscillates 4 times in 5,000 seconds
- Molecules of Protein2 are required for molecules of Protein1 to be created

Analytical vs Simulative Model Checking

david.gilbert@brunel.ac.uk

Analytical:

- **Exact** probabilities & prove properties
- A model state is an association of #molecules/levels to each of the species
  - **Protein1** has 10 molecules & **Protein2** has 20 molecules
- Analytical **assesses every state** that the model can be in (reachable states)
- **State space can grow even worse than exponentially** with increasing molecules, or even be infinite!

Simulative:

Instead of analysing the constructed state space**:**

- **analyse simulation outputs**
- Simulate the model X times and check these simulations
- Simulation run = finite path through the state space
- Can't prove probabilities

Simulative Model Checking

david.gilbert@brunel.ac.uk

In-line: check the observations as they arrive

>Requires complex computational machinery: ‘combine’ simulator & model checker

>Good for biochemical observations

>Don’t always need to finish the experimental run

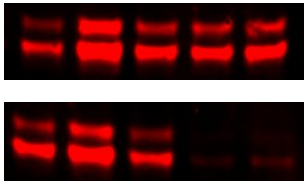
Off-line: check the observations after all have been generated

>Easier to implement computationally (simulate then check)

>Need to always define when to ‘stop’ generating observations

Simulation-based Model Checking Biochemical Pathways

david.gilbert@brunel.ac.uk



Property

Eg, “Order of peaks is RafP, MEKPP, ERKPP”

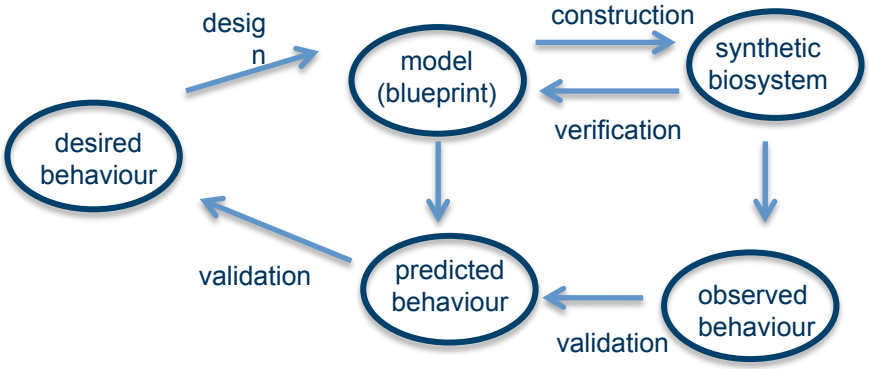
Time series data

Model

Lab

Behaviour Checker

Yes/no or probability



(P)LTL Linear Temporal Logic

G (φ) : φ always happens
F (φ) : φ happens at some time
X (φ) : φ happens in the next time point
φ_1 U φ_2 : φ_1 happens until φ_2 happens

Protein stability:

$P_{=?}$ [time >= 100 → ([Protein] >= 4 ^ [Protein] <= 6)]

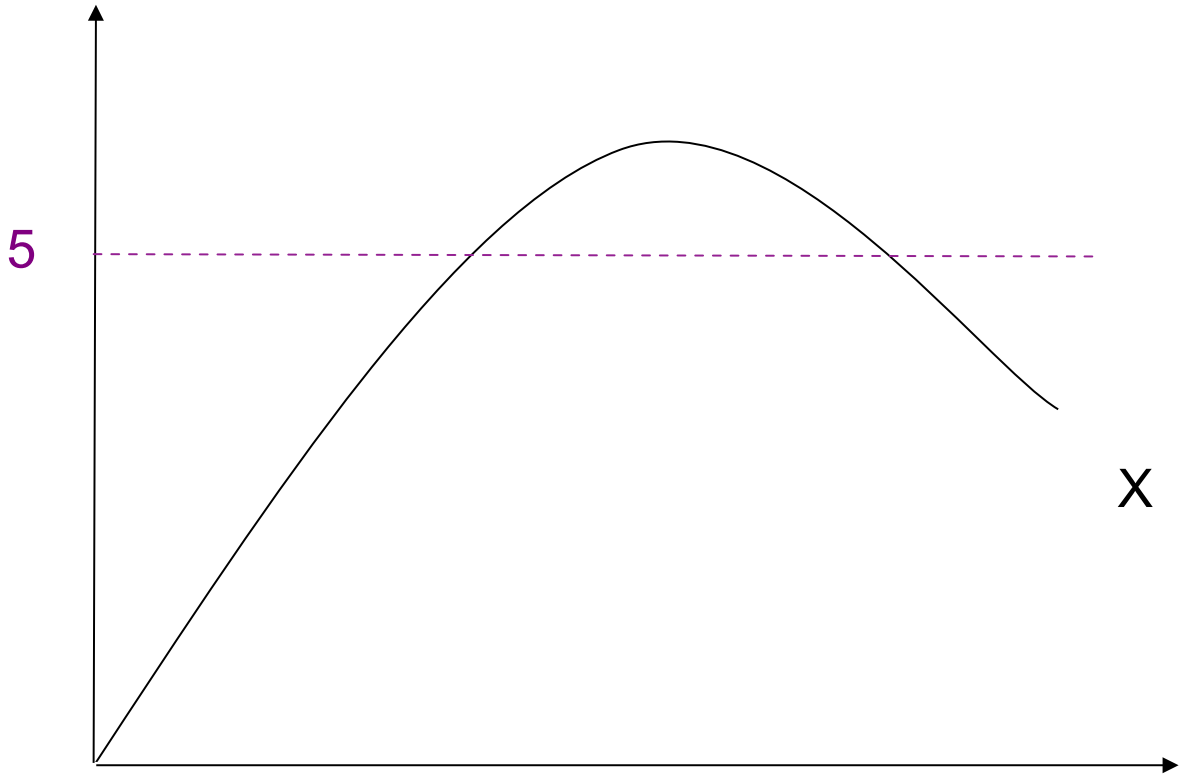
Protein concentration rises to a maximum value and then remains constant:

$P_{=?}$ [(d[Protein]> 0) U (G([Protein] >= 0.99*max[Protein]))]

MC2 with ODE Output

$$P_{=?}[\ F(\ X > 5\ )\ ]$$

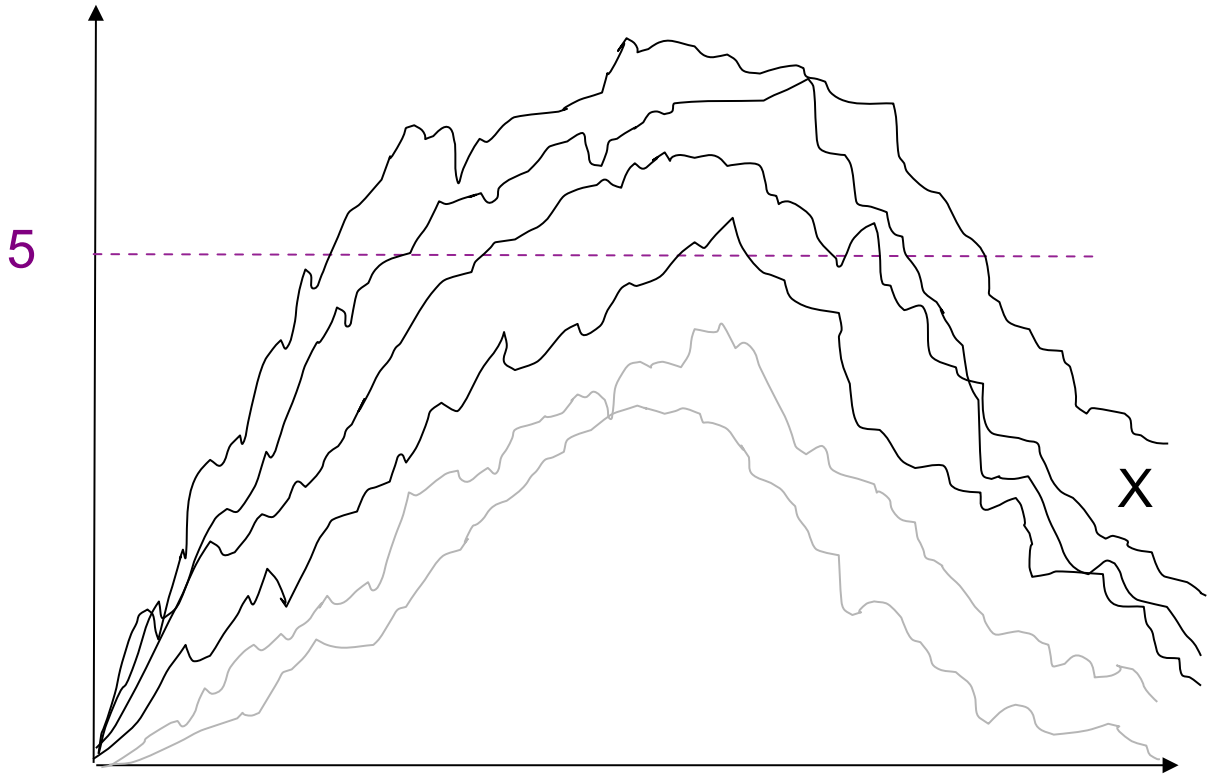
=> P = 1



MC2 with Gillespie Output

$$P_{=?}[\ F(\ X > 5\ )\ ]$$

=> P = 4/6



Qualitative to quantitative descriptions in PLTL

Qualitative:
Protein rises then falls

$$P=?\ [\ (\ d(\text{Protein}) > 0\ )\ U\ (\ G(\ d(\text{Protein}) < 0\ )\ )\ ]$$

Semi-qualitative:
Protein rises then falls to less than 50% of peak concentration

$$P=?\ [\ (\ d(\text{Protein}) > 0\ )\ U\ (\ G(\ d(\text{Protein}) < 0\ ) \wedge F\ (\ [\text{Protein}] < 0.5 * \max[\text{Protein}]\ )\ )\ ]$$

Semi-quantitative:
Protein rises then falls to less than 50% of peak concentration by 60 minutes

$$P=?\ [\ (\ d(\text{Protein}) > 0\ )\ U\ (\ G(\ d(\text{Protein}) < 0\ ) \wedge F\ (\ \text{time} = 60 \wedge \text{Protein} < 0.5 * \max(\text{Protein})\ )\ )\ ]$$

Quantitative:
Protein rises then falls to less than 100µMol by 60 minutes

$$P=?\ [\ (\ d(\text{Protein}) > 0\ )\ U\ (\ G(\ d(\text{Protein}) < 0\ ) \wedge F\ (\ \text{time} = 60 \wedge \text{Protein} < 100\ )\ )\ ]$$

Model searching

Peaks at least once

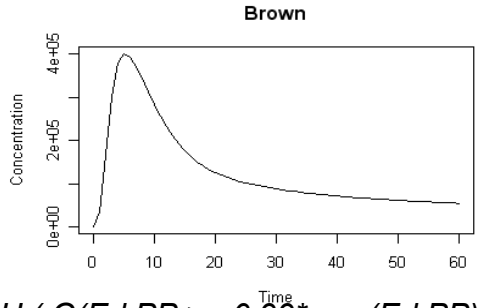
(rises then falls below 50% max concentration)

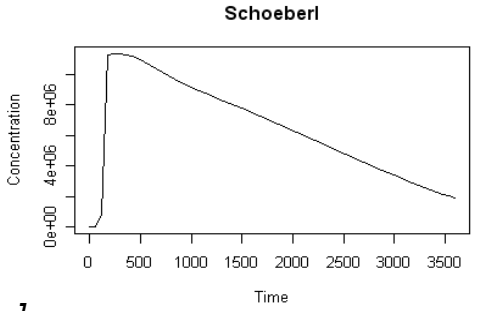
$P_{>=1}[\ ErkPP <= 0.50*max(ErkPP) \wedge d(ErkPP) > 0\ U\ (\ ErkPP = max(ErkPP) \wedge F(\ ErkPP <= 0.50*max(ErkPP)\ )\ )\ ]$

Brown

Kholodenko

Schoeberl



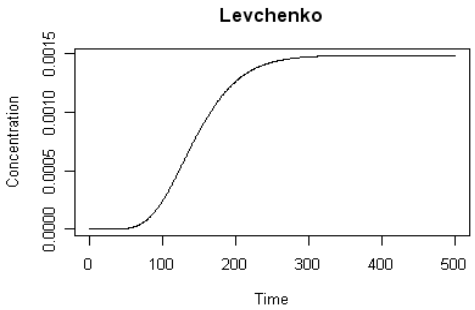


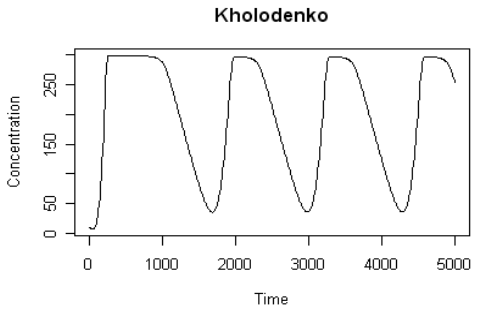
Rises and remains constant

(99% max concentration)

$P_{>=1}[ErkPP <= 0.50*max(ErkPP) \wedge (\ d(ErkPP) > 0\ )\ U\ (\ G(ErkPP >= 0.99*max(ErkPP))\ )\ ]$

Levchenko



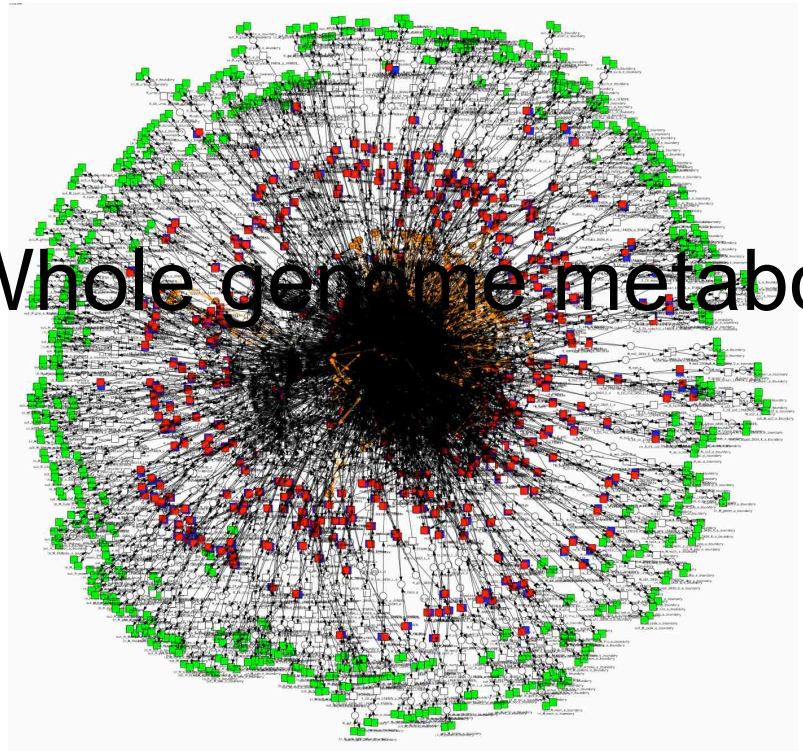


Oscillates at least 4 times

$P_{>=1}[\ F(\ d(ErkPP) > 0 \wedge F(\ d(ErkPP) < 0 \wedge \ldots)\ )\ ]$

Kholodenko

Model checking over large amount of data



Whole genome metabolic model (*E.coli)*

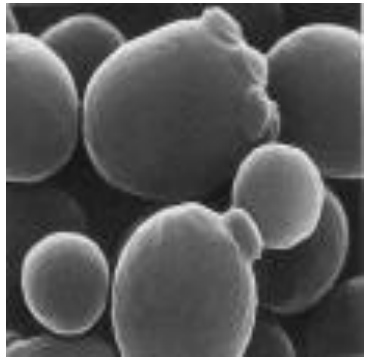
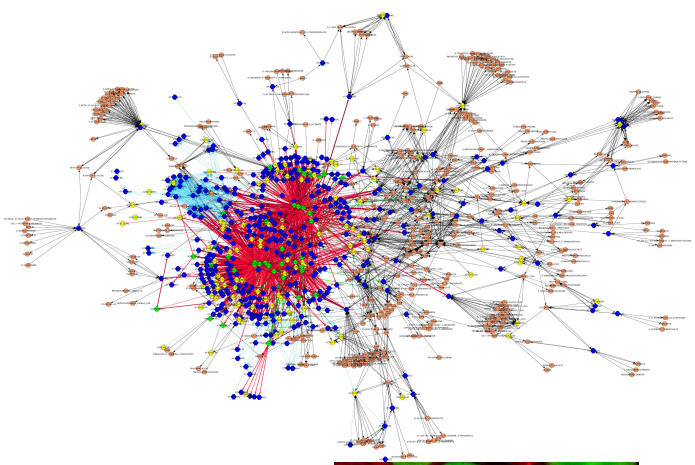
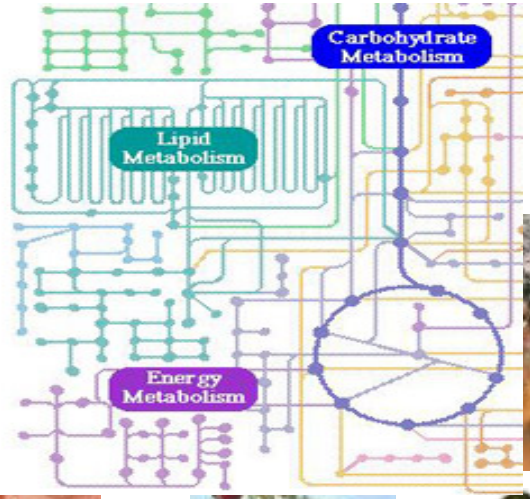
What about scaling up?

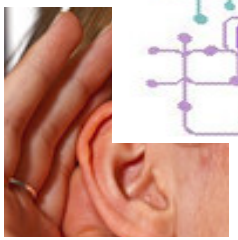
david.gilbert@brunel.ac.uk

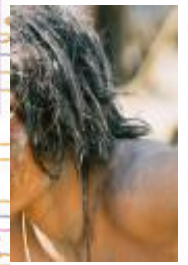


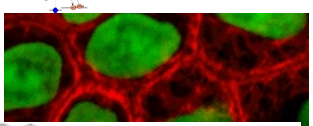
Multiscale Modelling in Biology

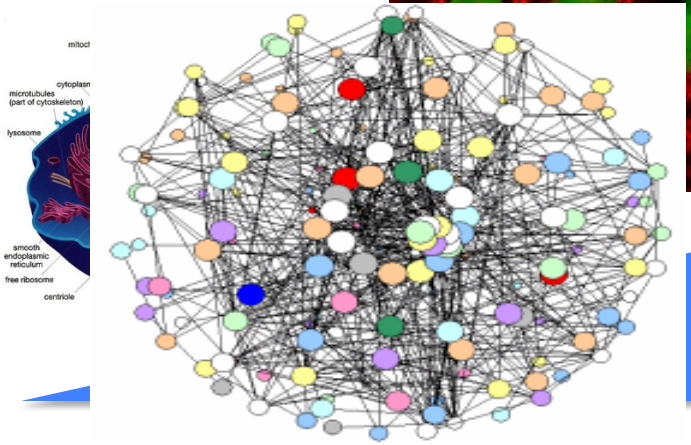


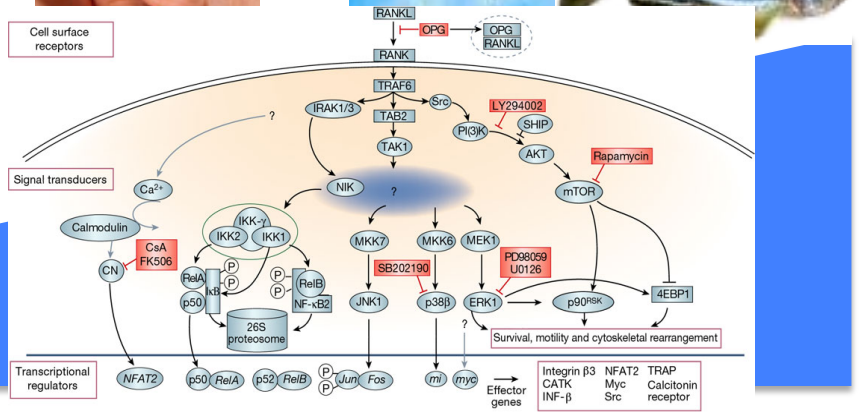






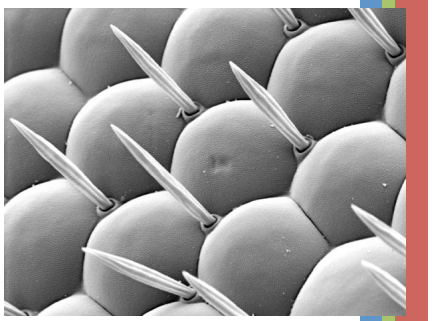






Multiscale Modelling Challenges

david.gilbert@brunel.ac.uk

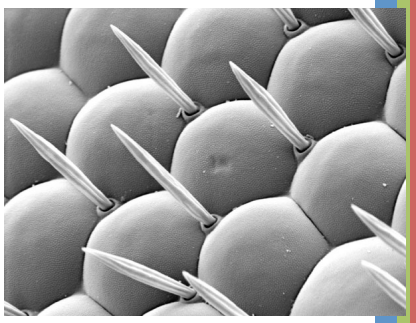


Repetition – multiple components with similar definitions
Variation – genetic mutants; random variants
Organisation - regular / irregular patterns in 1, 2 or 3 dimensions
Communication – short & long distance
Hierarchical organisation – intra or inter cellular (tissues, organs, …)
Movement – mobility (passive) & motility (active)

(Components could be molecules, organelles, cells, tissues, organs, organisms.)

…Multiscale Modelling Challenges

david.gilbert@brunel.ac.uk

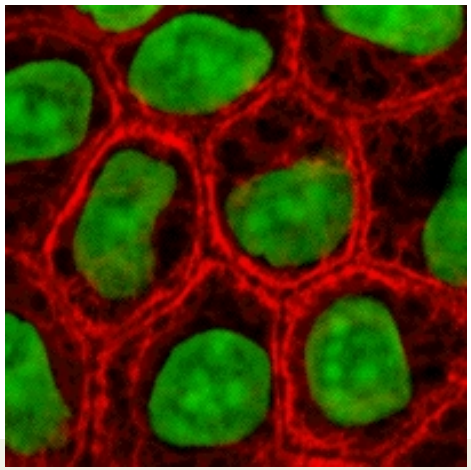


Replication - reproduction
Deletion – cell death
Irregular/semi-regular organisation of components – for example a not-exact honeycomb grid.
Dynamic grid size – for example alter size and/or topology of grid to model development. Also required for ability to insert/remove items.
Differentiation of components - for example, differentiation of embryonic stem cells or immune cells makes a less specialized cell more specialized.
Pattern formation of components - organizing a number of cells in appropriate one, two or three dimensional structures in space and time.

david.gilbert@brunel.ac.uk

Repetition of individual components

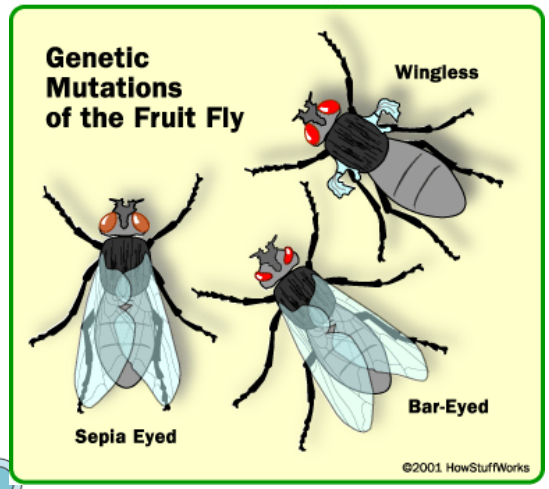
Components within a cell (organelles etc)
Multiple cells each of which having a similar definition
Repeated tissue fragments
Repeated organs (wings,…)
Repeated individual organisms

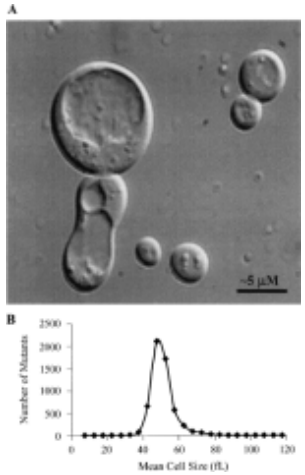


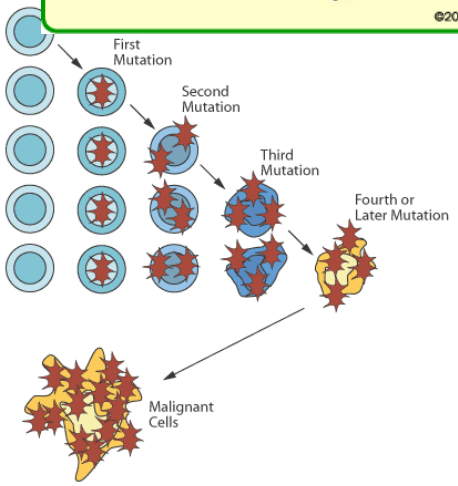
Variation

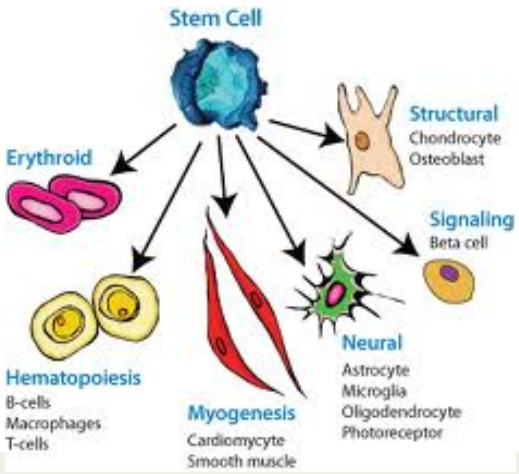
david.gilbert@brunel.ac.uk

Sets of similar components with defined variations
Random mutation
Genetic mutants
Cancerous tissue
Differentiation







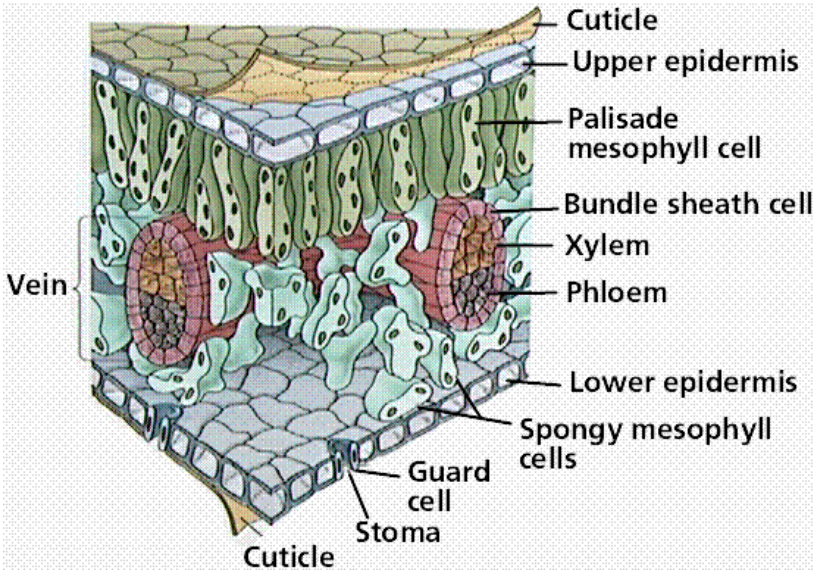


Spatial organisation

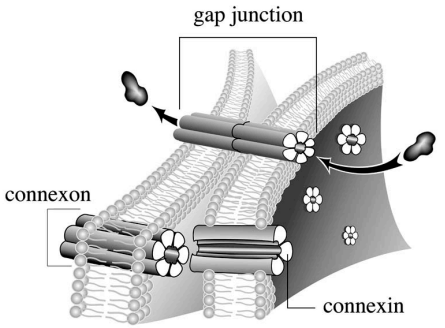
david.gilbert@brunel.ac.uk

Between cells

>how they are organised into regular or irregular patterns over spatial networks in one, two or three dimensions.

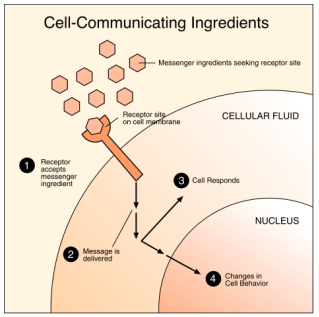


Communication



Between **immediate neighbours** (intracellular complexes)
Long-distance (cytokines etc)

Further constraints:
Type of **relationship** between partners
Type of component(s)
History of component(s)
Position of component(s) in spatial network.



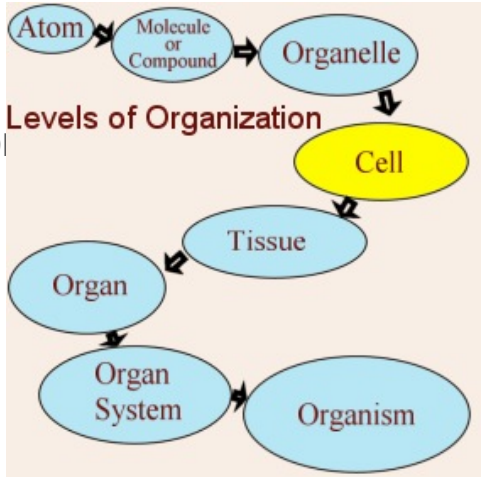
Hierarchical organisation

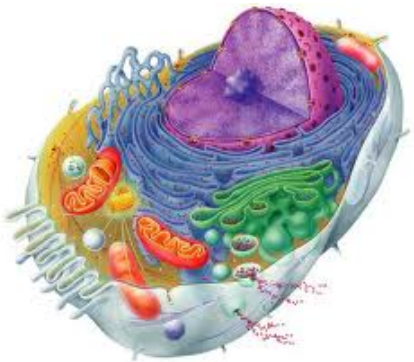
david.gilbert@brunel.ac.uk

Components containing repeated sub-components

Cell containing several compartments /components.

Enables the use of abstraction over level of detail used to describe co





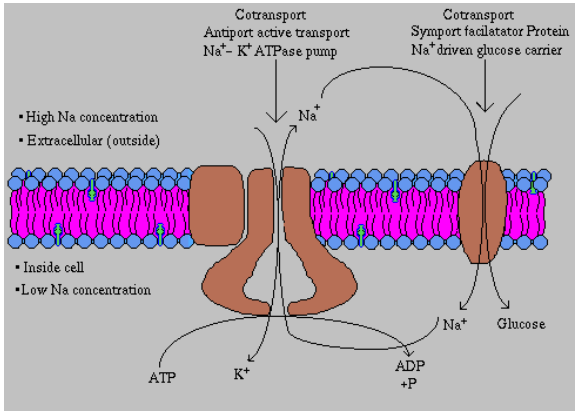
Movement

david.gilbert@brunel.ac.uk

Mobility – passive movement.

Protein transport

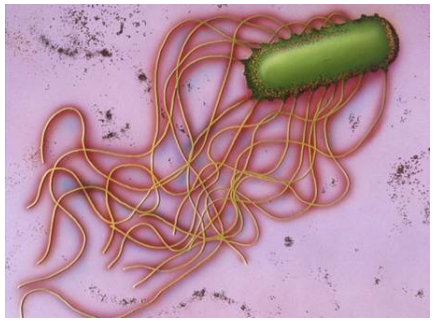
Sodium transport

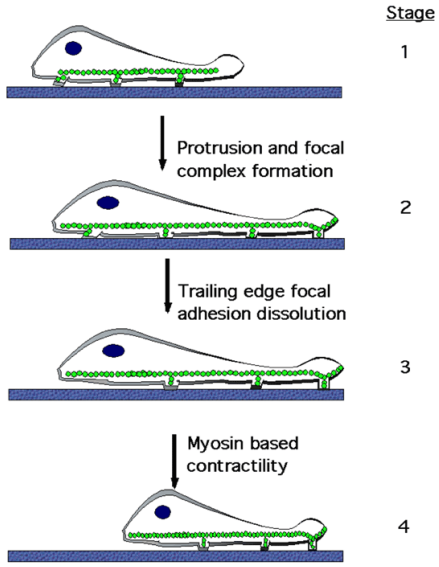


Motility – active movement.

Cells using organelles (flagellae)

General cellular motility



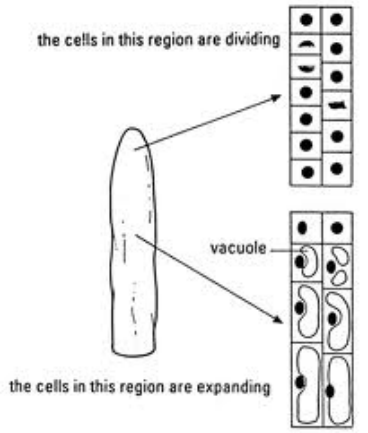


Replication

david.gilbert@brunel.ac.uk

E.g. cell division

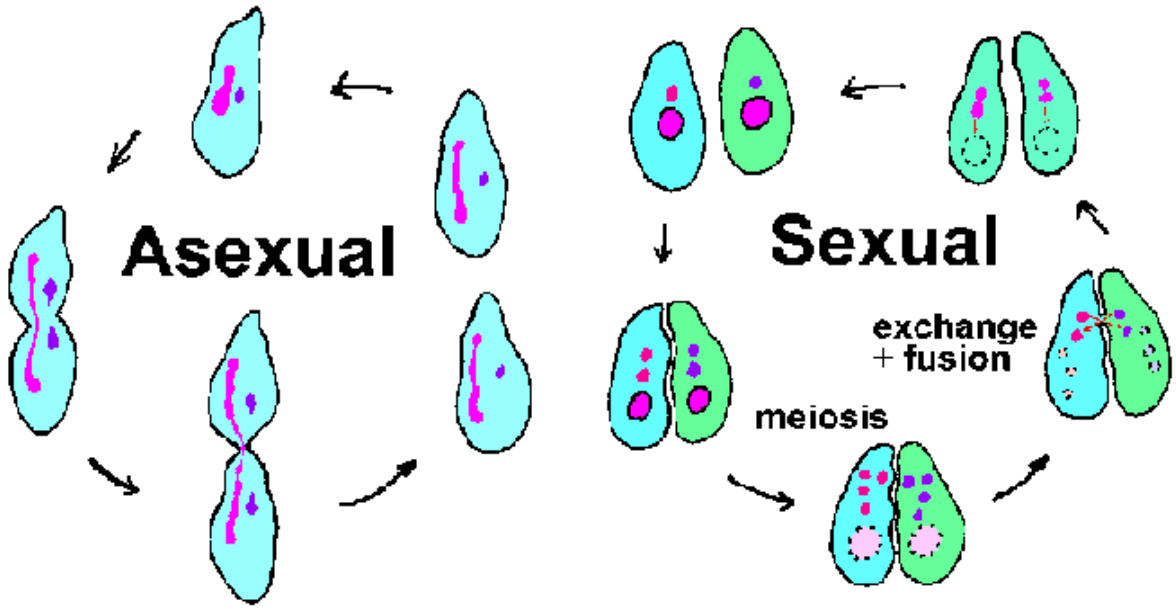
Can take into account:
Mutation
Spatial organisation / position



Exchange

david.gilbert@brunel.ac.uk

Exchange of (genetic) information
Sexual
Asexual



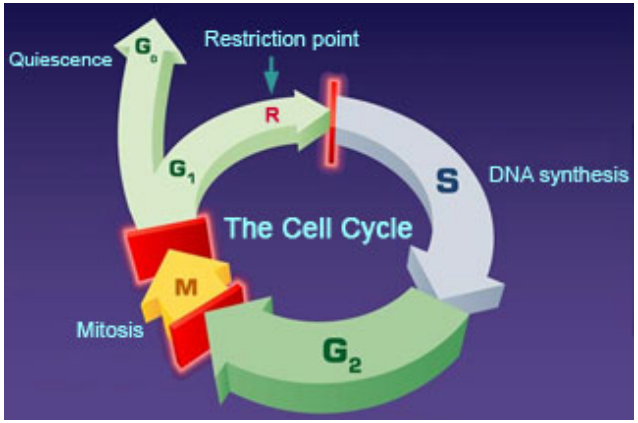
Death etc

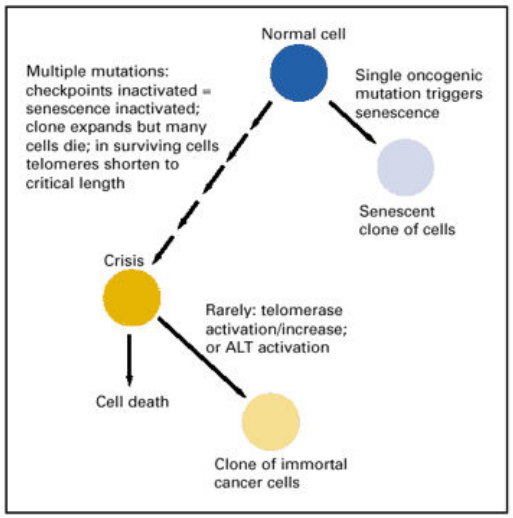
Cell death:

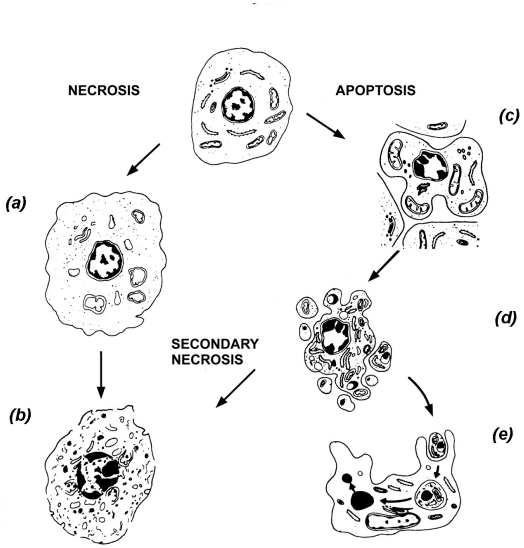
>apoptosis (programmed), necrosis (traumatic)

Quiescence

Senility







Coloured Petri Nets

{david.gilbert,ovidiu.parvu}@brunel.ac.uk

Permit
Repeated elements
Discrimination of species (molecules, metabolites, proteins, secondary substances, genes, etc.).
Locality: distinguish between sub-populations of a species in different locations (cytosol, nucleus and so on).

D. Gilbert, M. Heiner, F. Liu and N. Saunders (2013): Colouring Space - A Coloured Framework for Spatial Modelling in Systems Biology. In Proc. PETRI NETS 2013. Springer LNCS, 7927, 230-249.

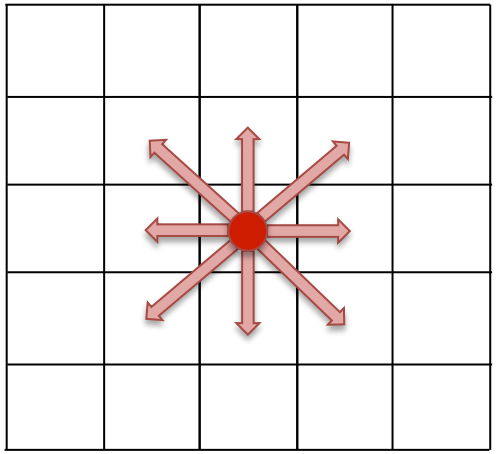
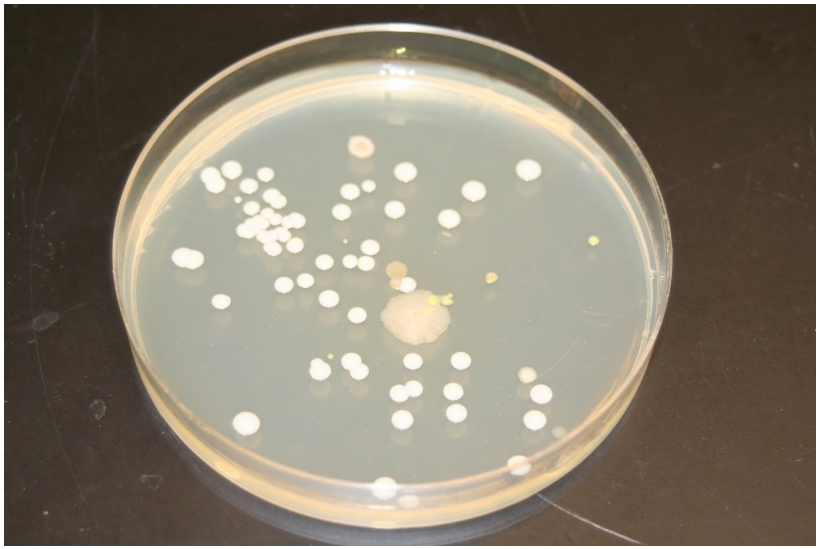
•**Cell division**: process by which a *parent cell* divides into two or more *daughter cells*.





Bacterial colony

{david.gilbert,ovidiu.parvu}@brunel.ac.uk

Specification

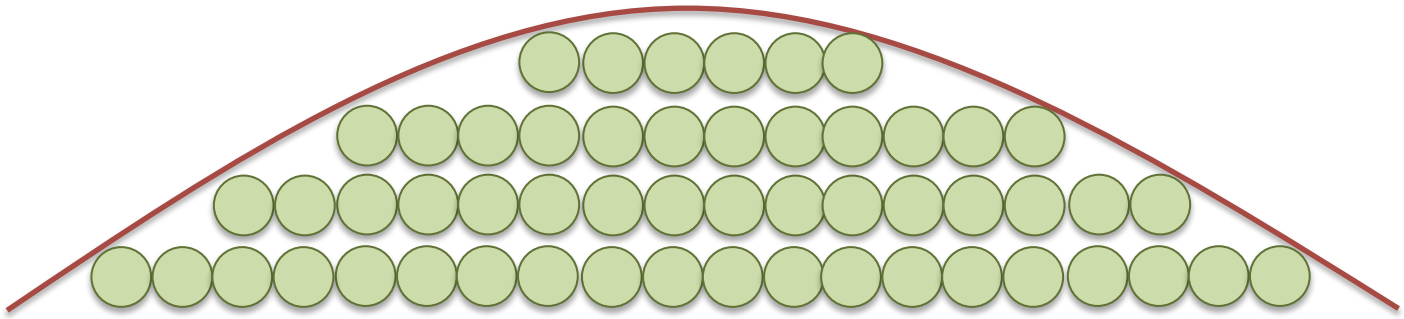
{david.gilbert,ovidiu.parvu}@brunel.ac.uk

- Starts with only **one** cell or organism
- **Dimensions** of the environment are fixed
- Division of the cells/organisms is **random/ stochastic**
- A **maximum capacity** or volume for each position in the grid

Colony profile

{david.gilbert,ovidiu.parvu}@brunel.ac.uk

•The **maximum height** of the colony of bacteria is limited due to:

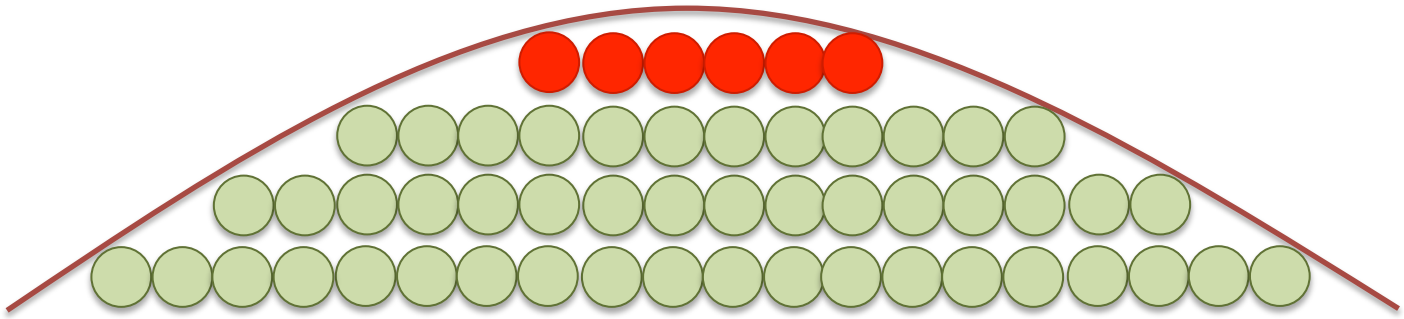


Colony profile

{david.gilbert,ovidiu.parvu}@brunel.ac.uk

- The **maximum height** of the colony of bacteria is limited due to:

1. Lack of **nutrients** for the bacteria at the top

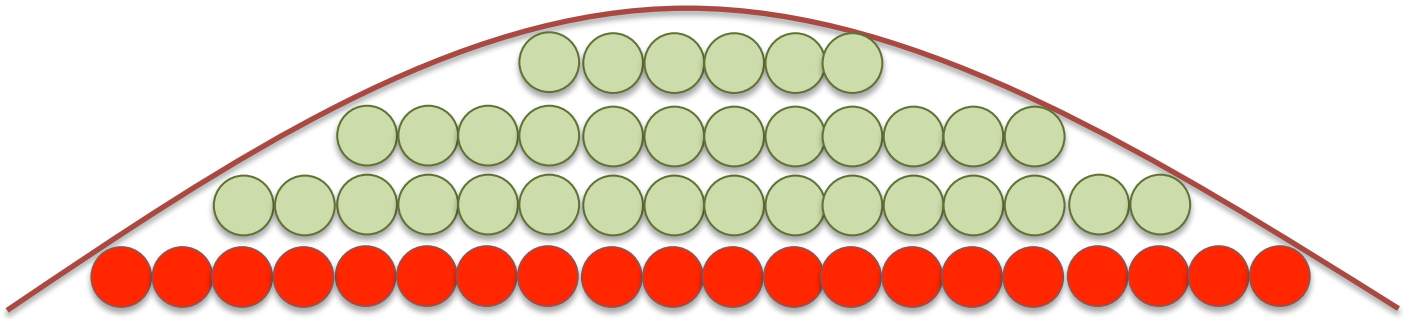


Colony profile

{david.gilbert,ovidiu.parvu}@brunel.ac.uk

•The **maximum height** of the colony of bacteria is limited due to:

1. Lack of **nutrients** for the bacteria at the top
2. Lack of **oxygen** for the bacteria at the bottom



Specification

{david.gilbert,ovidiu.parvu}@brunel.ac.uk

- Starts with only **one** cell or organism
- **Dimensions** of the environment are fixed
- Division of the cells/organisms is **random/ stochastic**
- A **maximum capacity** or volume for each position in the grid
- Whenever cellular division occurs the **parent cell** preserves its position, **offspring cell** may be (probabilistically) displaced to neighbouring positions

Constructing the model

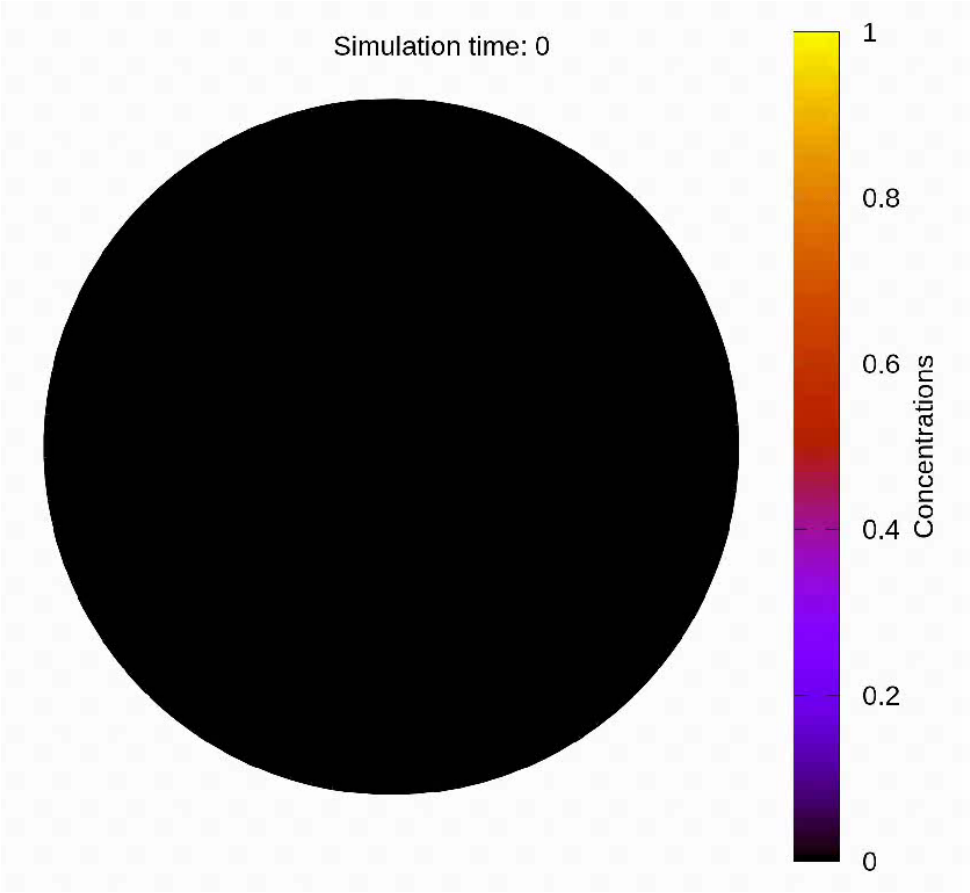
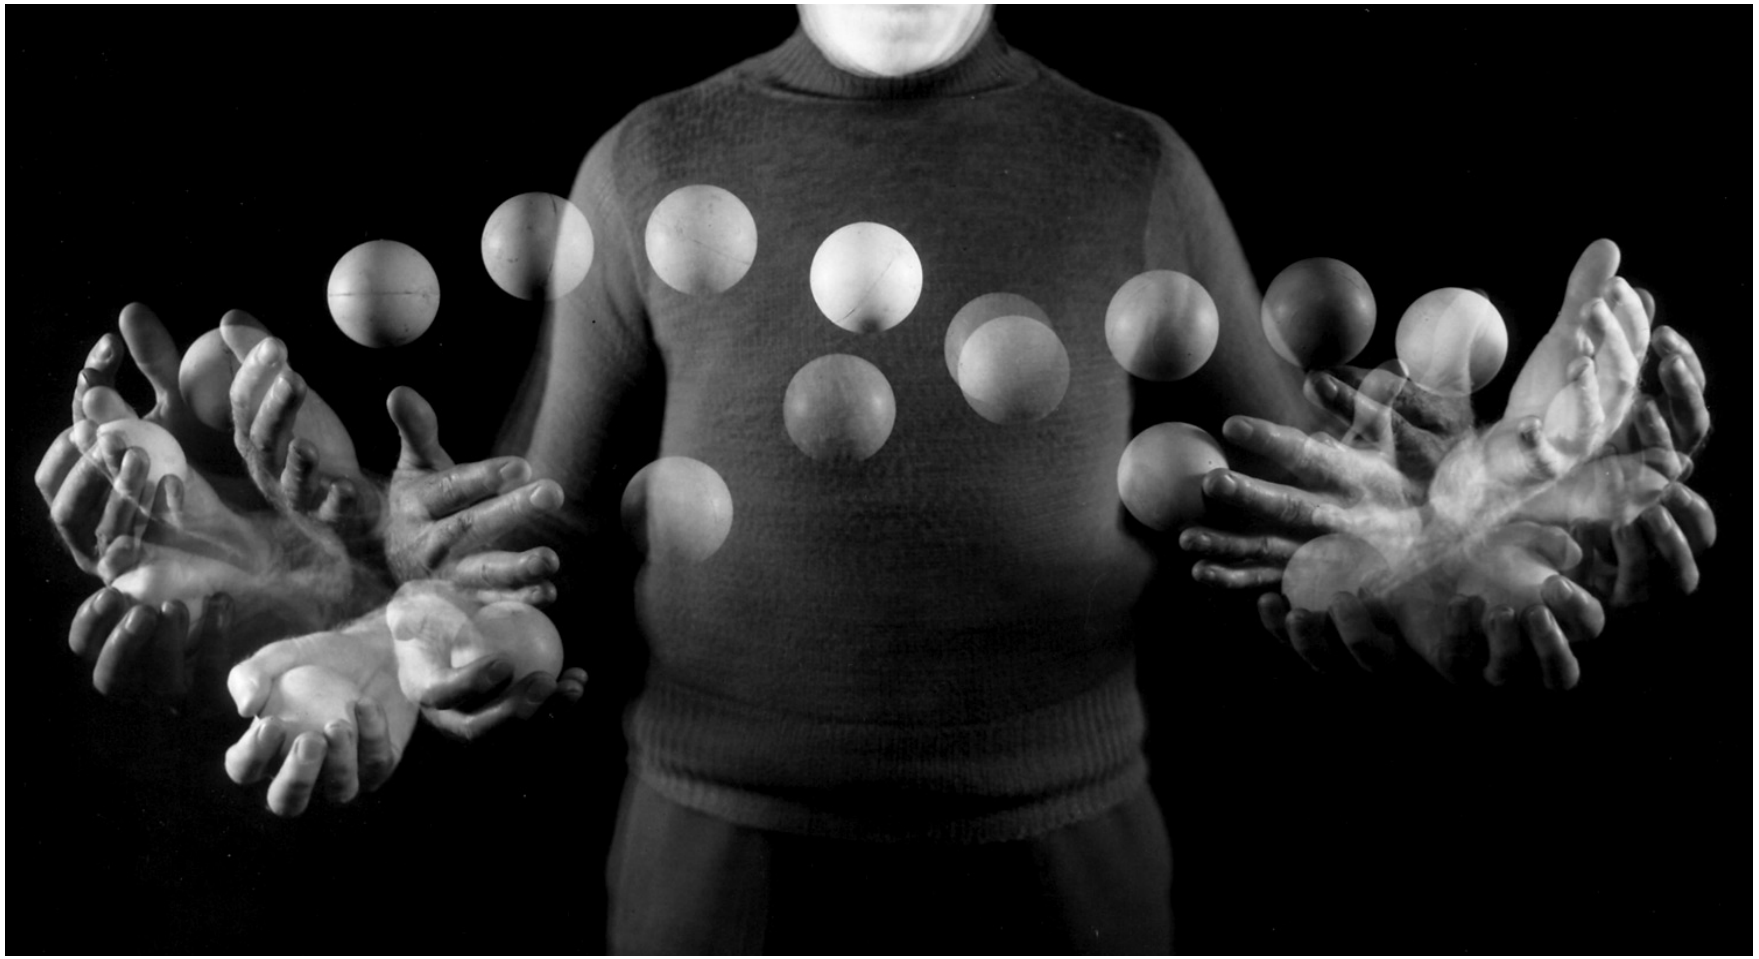
Phase variation model simulations

{david.gilbert,ovidiu.parvu}@brunel.ac.uk



Movement….

{david.gilbert,ovidiu.parvu}@brunel.ac.uk



Movement: Approach 1

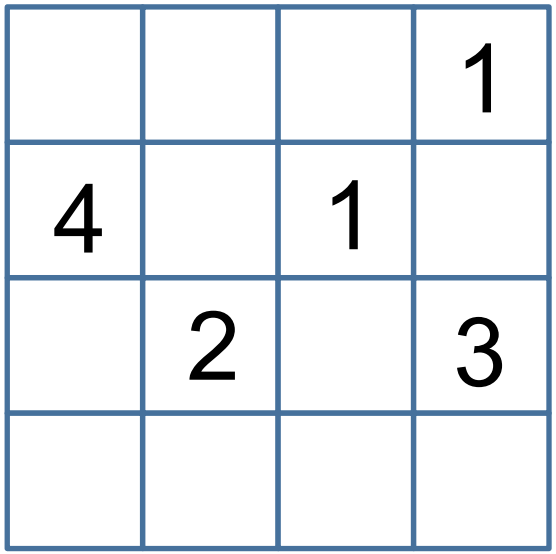
{david.gilbert,ovidiu.parvu}@brunel.ac.uk

2D

Model space using a **grid** with (x, y) colour tuples and use a count for the number of agents per grid position

Advantage:

Memory efficient



Disadvantage:

Agents do not have a state

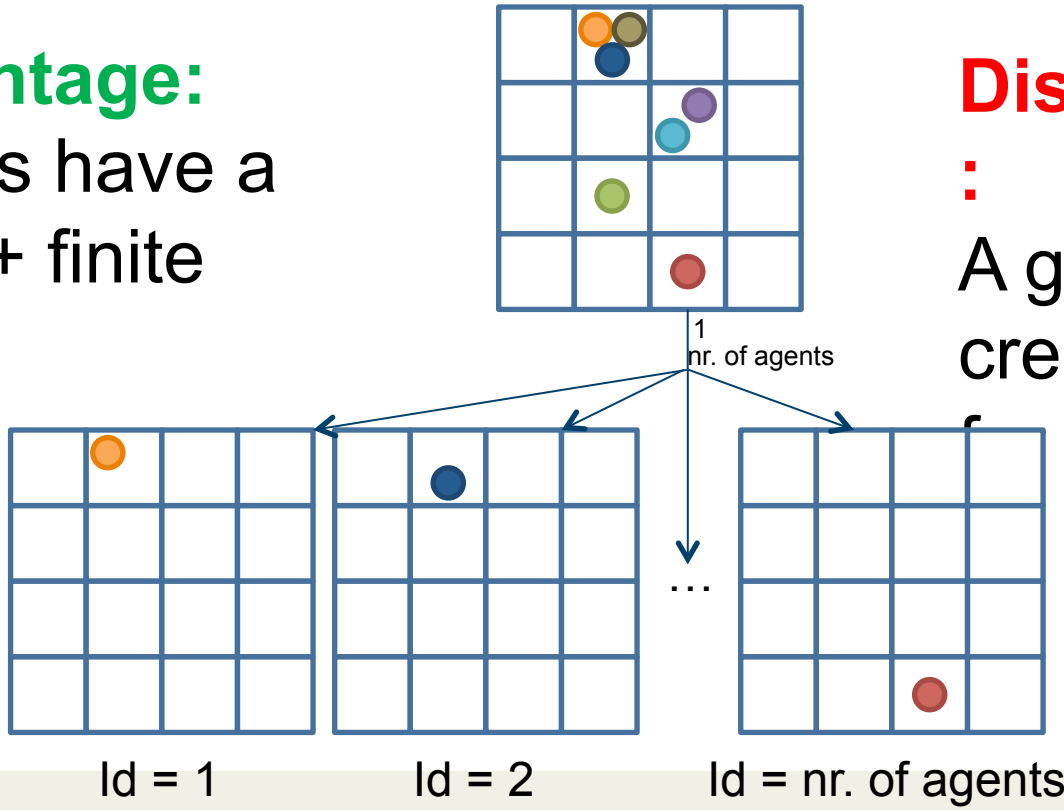
Movement: Approach 2

{david.gilbert,ovidiu.parvu}@brunel.ac.uk

2D

Model each **agent** with an Id and mark the position(s) (X, Y) it occupies

Advantage:
Agents have a state + finite space



Disadvantage:
A grid is created for each agent

Movement: Approach 3

{david.gilbert,ovidiu.parvu}@brunel.ac.uk

2D

Model every **agent** as two places “x” and “y” where each place gets a colour tuple Id

Advantage:

Memory efficient and agents have a state

Id	X	Y
1	1	2
2	3	4
…	…	…
Nr. of agents	1	3

Disadvantage:

Higher runtime effort (state-dependent rates requires special tool support)

Multiscale: from signalling to organs

{david.gilbert,ovidiu.parvu}@brunel.ac.uk

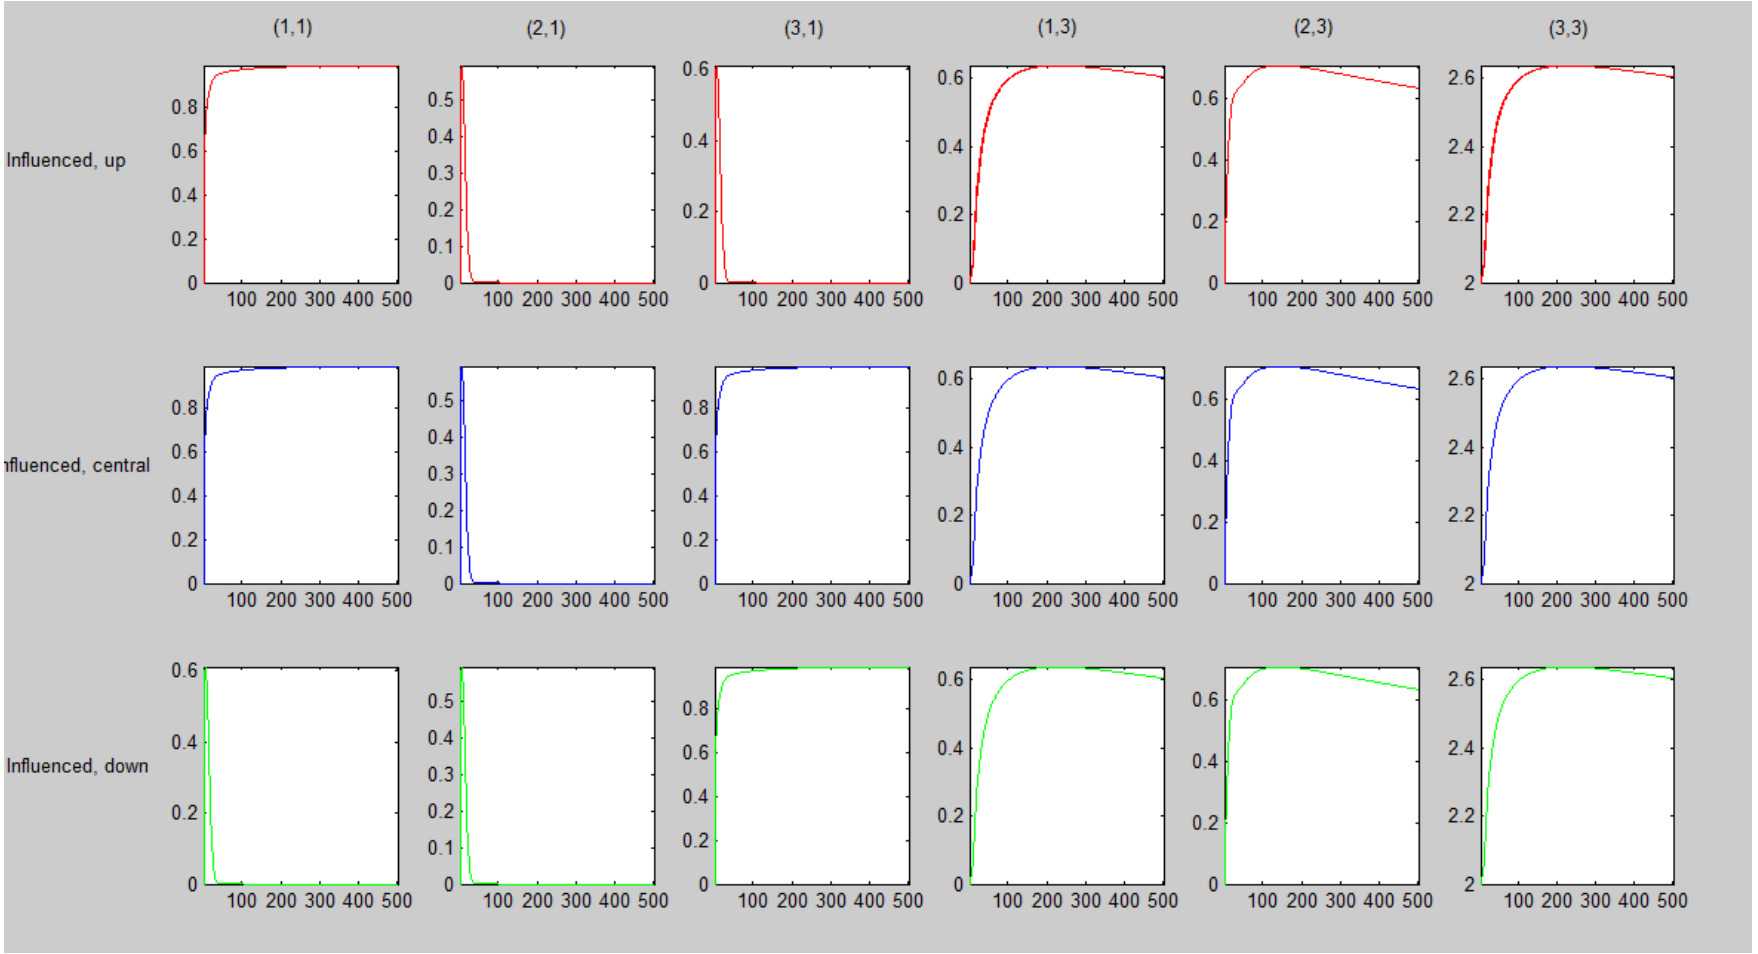
Model checking

Clustering of behaviours

david.gilbert@brunel.ac.uk

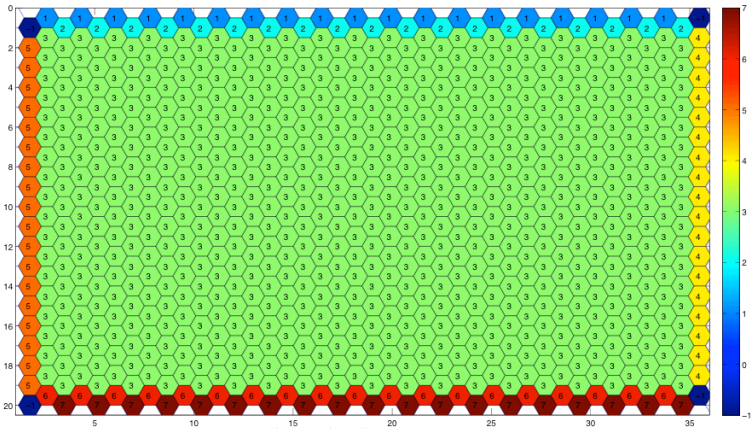


Clustering

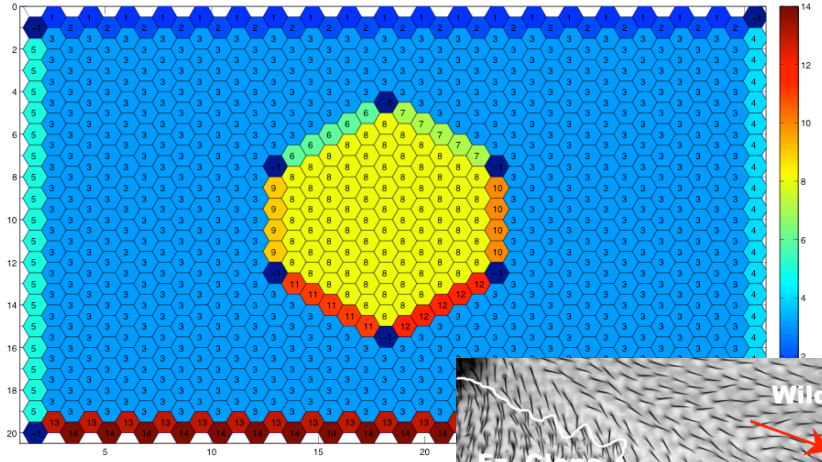
david.gilbert@brunel.ac.uk

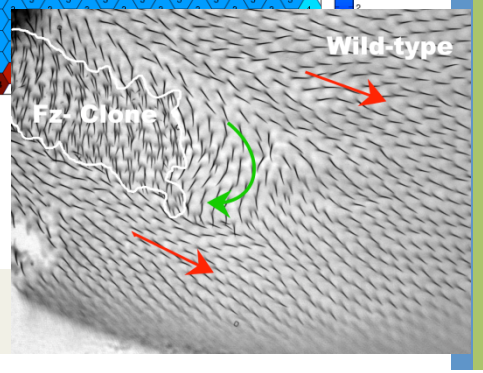
DBScan with Principal Component Analysis (PCA)

Unbiased model:
Grid 40*40 (800 cells)

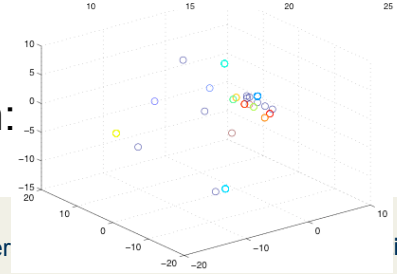


Fz- mutant clone model:
A patch of mutated cells lacking Frizzled (Fz) in a wild-type background





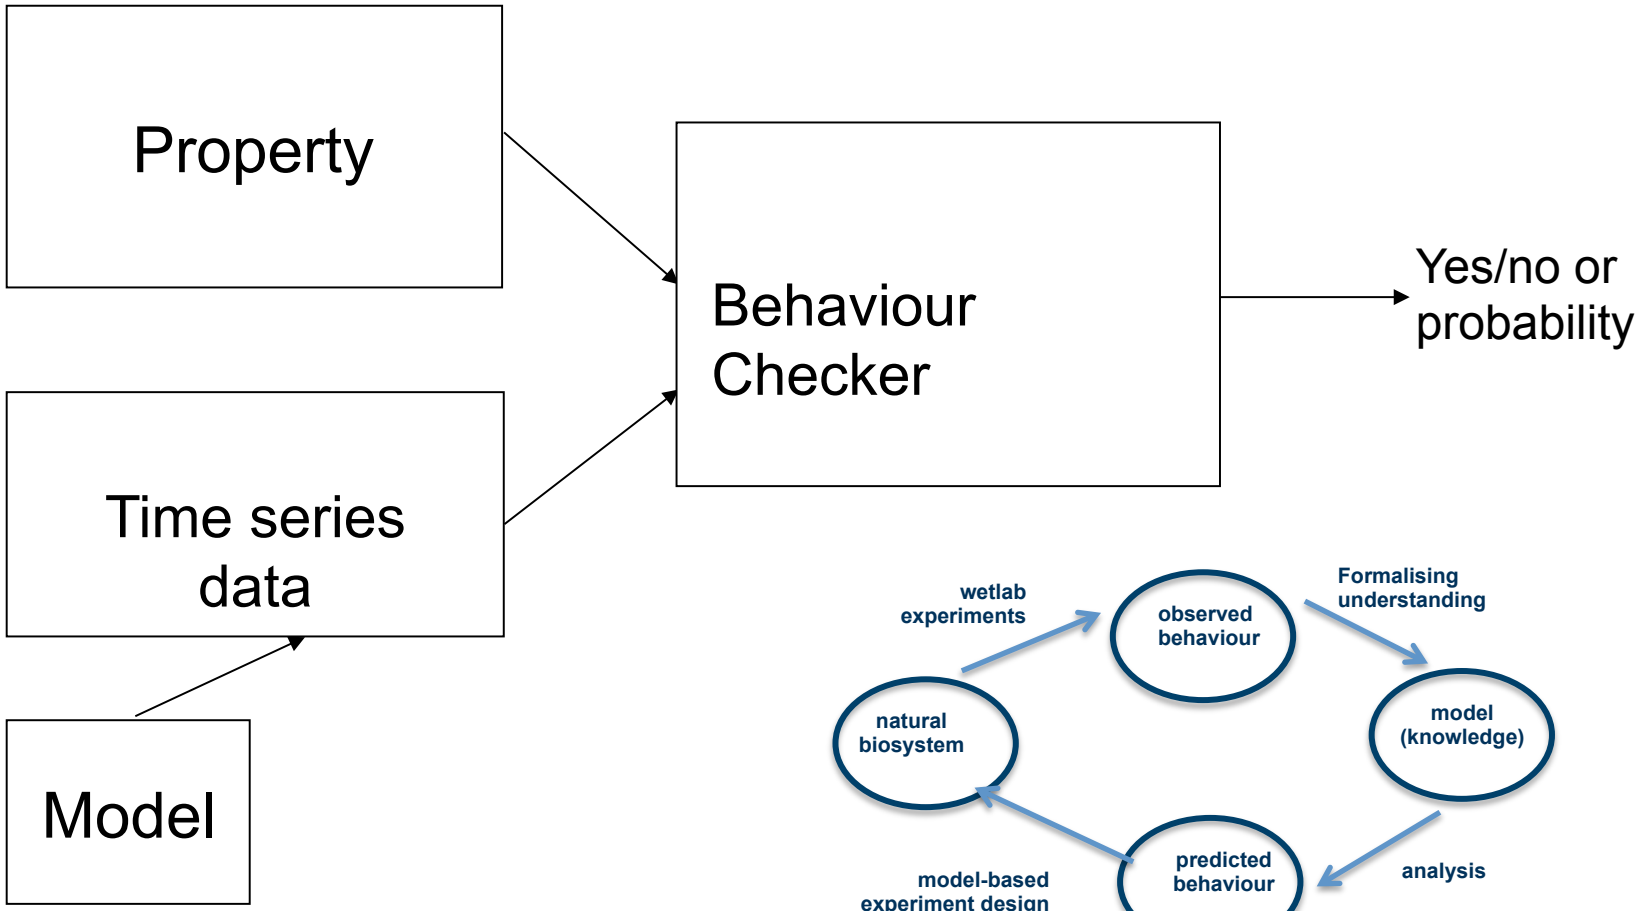
Feature selection: PCA

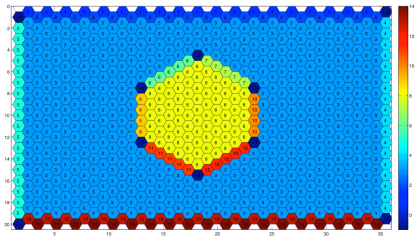


Simulation-based Model Checking

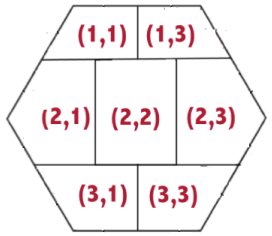
david.gilbert@brunel.ac.uk

- PLTL using MC2 [Donaldson&Gilbert CMSB 2008]





Model Checking
Primary data



Fz- mutant clone model

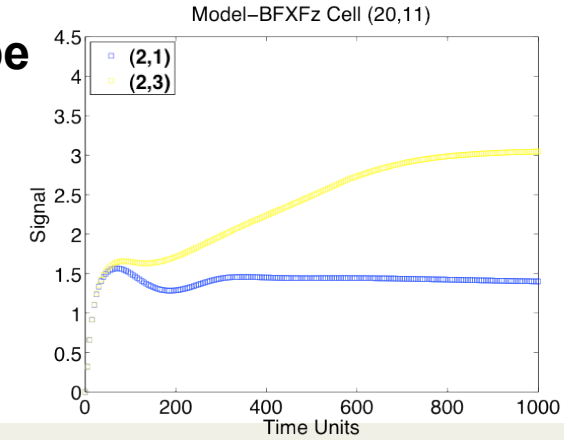
Unlike in the wild-type cells, for the **cells distally neighbouring to the Fz- clone** the concentration of FFD in the middle distal compartment is always lower than that of the middle proximal compartment:

P=? [time > 0 → G(D2 < P2)]

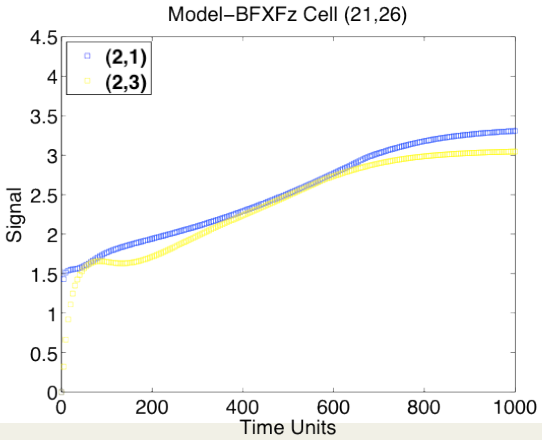
Moreover, the trace of D2 exhibits a peak followed by a trough, which is not true for P2:

P=?[F(d(D2) > 0 ∧ F(d(D2) < 0 ∧ F(d(D2) > 0)))]

Wild-type



Distally neighbouring to the clone

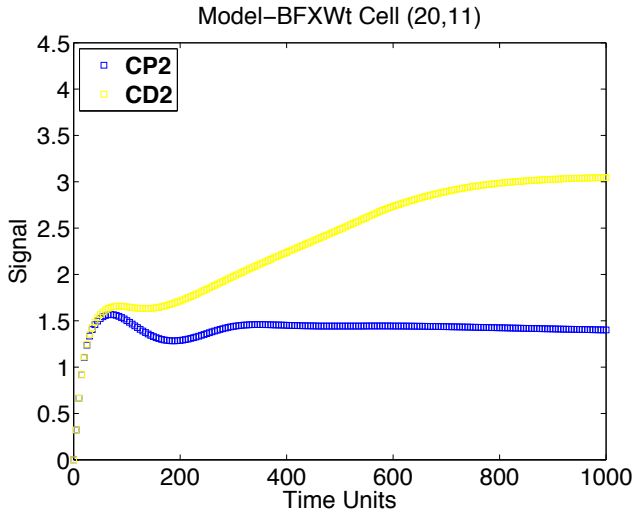


Big idea – check cumulative signal!

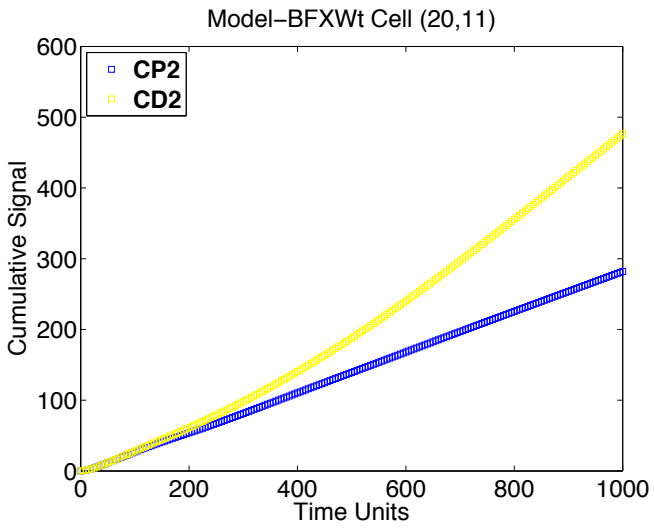
david.gilbert@brunel.ac.uk

- Cumulative signal: time-series of accumulated concentrations of FFD (secondary data)
- Why?

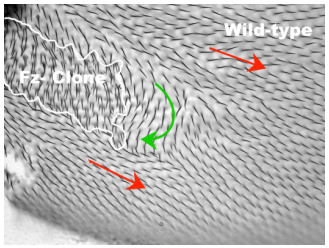
- The localisation of PCP signalling at any given time point is the result of the cumulative effect of the sum over the signalling events until that point.



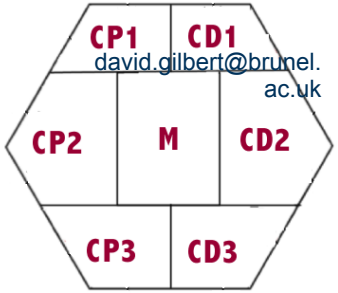
Primary data



Secondary data



Model Checking
Secondary data
Fz- mutant clone model



david.gilbert@brunel.ac.uk

Wild type cells in the tissue (i.e. away from the clone area).
After short initial period: Always middle distal cumulative[FFD] greater than middle proximal cumulative[FFD]

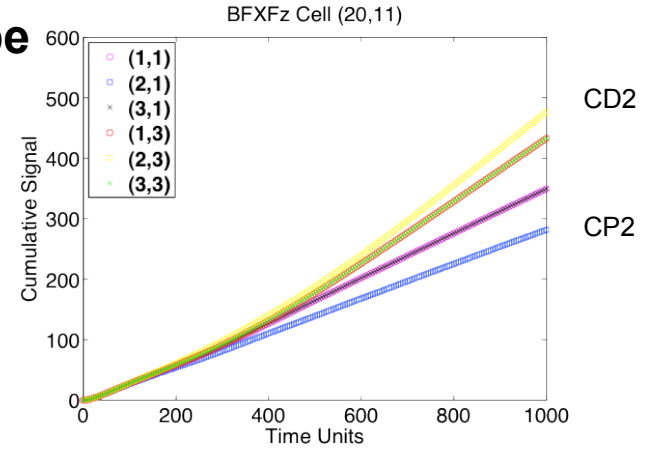
P=? [time > ε → G(CD2 > CP2)]

Wild type cells distally neighbouring to clone in the tissue
After short initial period: Always middle distal cumulative[FFD] less than middle proximal cumulative[FFD]

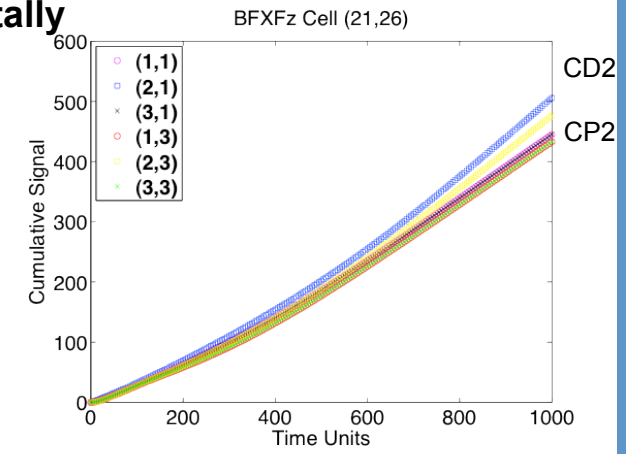
P=? [time > ε → G(CD2 < CP2)]

Hairs grow normally in wild-type, but disturbed in WT distally near clone, influence from the clone

Wild-type



Wild-type distally neighbouring to clone



Automatic Generation of Temporal Logic Descriptions

We can use PLTLc to characterise the clusters of time series

PLTLc statements should be

- *general* enough to describe all the time series in a given cluster
- *discriminative* enough to distinguish between time series of different clusters

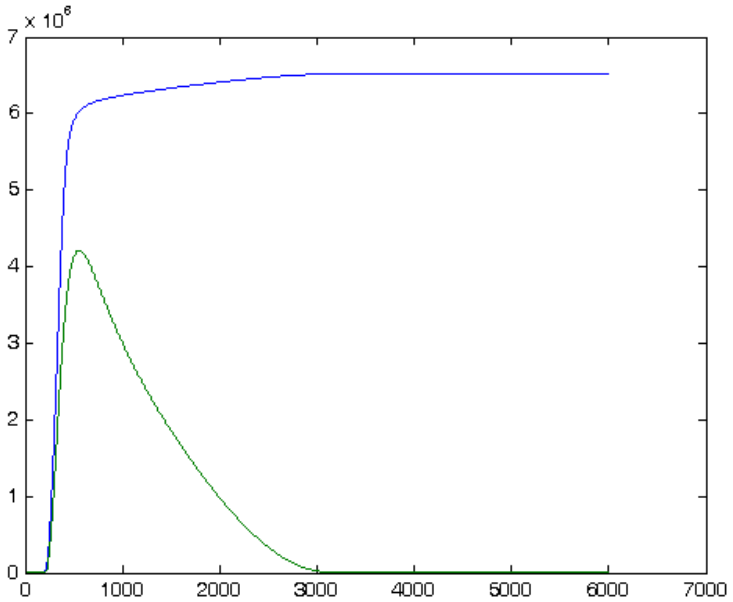
The generation algorithm is based on property patterns (templates)

D. Maccagnola, E. Messina, Q. Gao and D. Gilbert, (2012). A Machine Learning Approach for Generating Temporal Logic Classifications of Complex Model Behaviours. Proc Winter Simulation Conference 2012, IEEE.

Automatic Generation of TL Descriptions

• ***Trend***: describes the trend of a time series as a sequence of direction (“increase”, “steady”, “decrease”)

$$\phi_1 U(\phi_2 U(\ldots U(\phi_{m-1} U(G(\phi_m)))\ldots))$$



If a cluster shows different trends, they are ordered by frequency (F_0 is the most frequent, then F_1 and so on) and the cluster trend is defined by:

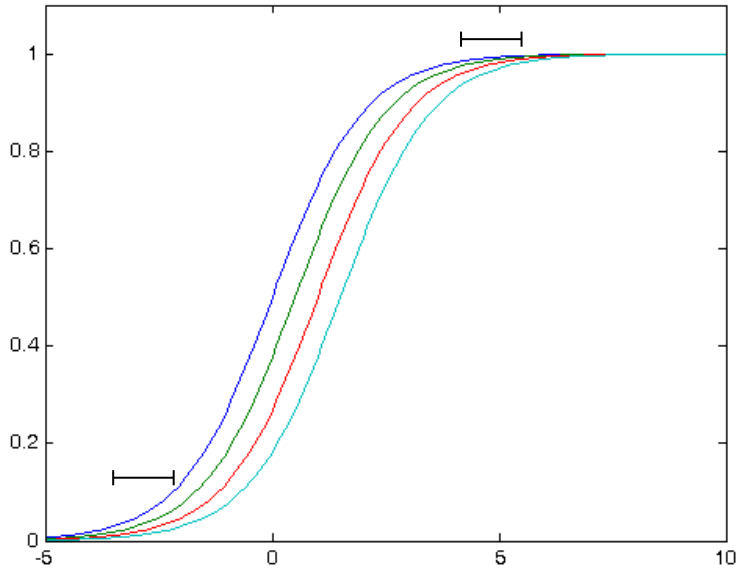
F_0 V F_1 V F_2 V …

Example:
steady-increase-steady OR
steady-increase-decrease-steady

d = 0 U d > 0 U (G(d=0)) V
d = 0 U d > 0 U d<0 U (G(d=0))

Automatic Generation of TL Descriptions

- ***Time***: identifies the time points when the time series changes its direction, i.e. a set of “direction changes”

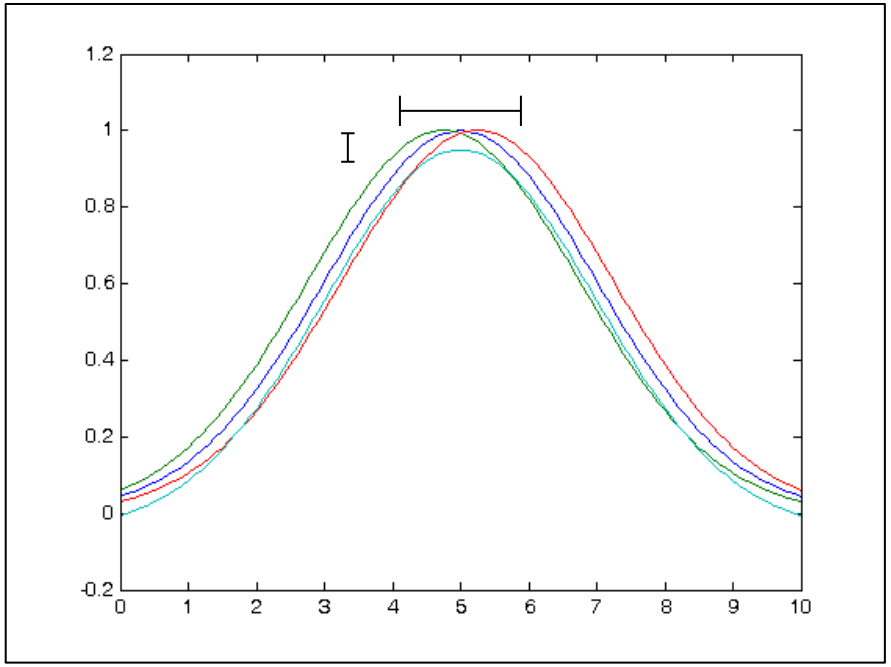


Time series with the same trend may have slightly different time patterns

We compute a set of *time intervals*

Automatic Generation of TL Descriptions

• ***Extrema***: represents the occurrence of all the local minima and maxima of a time series

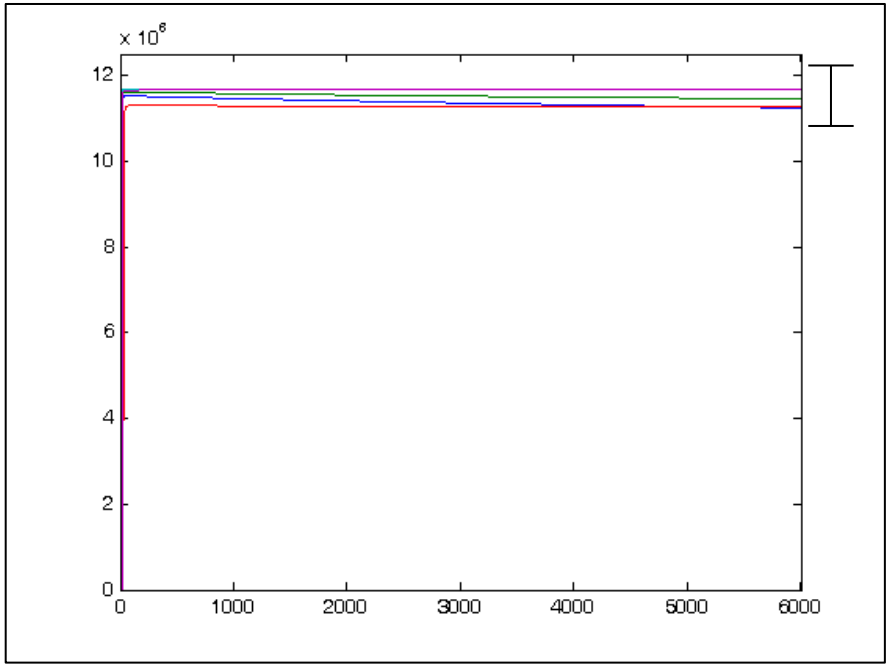


The time and value of each extrema can slightly change among the time series in a cluster

The extrema of a cluster are defined by a sequence of *time* and *value* intervals

Automatic Generation of TL Descriptions

• ***Steady state***: represents the value of the time series steady state (if exists)



The value of each steady state can slightly change among the time series in a cluster

The steady state of a cluste, if exists, is defined by a value interval

Automatic Generation of TL Descriptions

PLTLc GENERATION PROCEDURE:

1. Consider cluster C_i and the set of remaining clusters $\neg C_i$;
2. If C_i and $\neg C_i$ have different trends, stop; otherwise, continue;
3. If C_i and $\neg C_i$ have the same trend with different times, stop; otherwise, continue;
4. If C_i and $\neg C_i$ have at least one different extrema, stop; otherwise, continue;
5. If C_i and $\neg C_i$ have different steady states, stop; otherwise, the clusters are identical and the algorithm cannot return a valid description.

Automatic Generation of TL Descriptions

- The effectiveness of this algorithms is affected by:
    - The cluster's quality
    - The number of "direction changes" of the time series
- The effectiveness of this algorithm is NOT affected by the *number of time series* per cluster

Automatic Generation of TL Descriptions

Evaluation

• To evaluate the PLTLc statement, we test it as a temporal logic query over the clusters

• We use the probability $P_{=?}[\phi_{opt}(C_i)]$ that the statement correctly classifies the time series belonging to cluster *i*

•We associate to each statement a "confidence level" *Conf :*

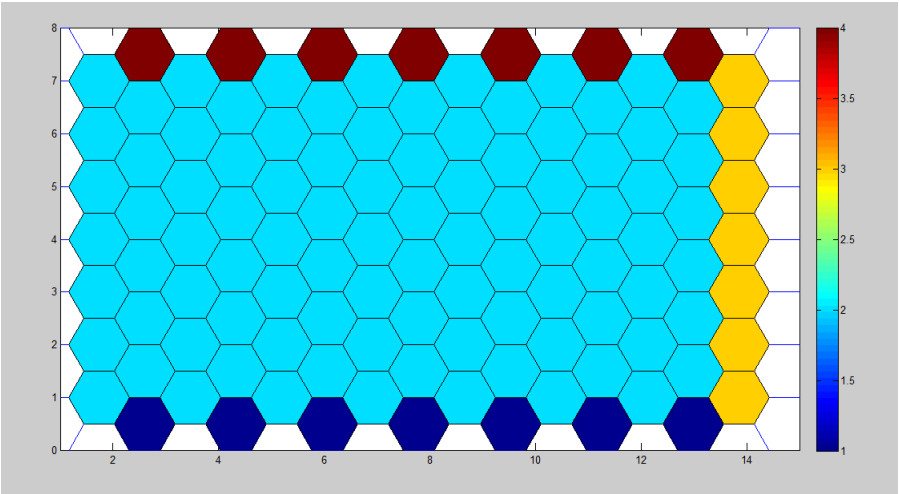
$$Conf(\phi_{opt}(C_i)) = \frac{P_{=?}[\phi_{opt}(C_i)]}{1 + max_{j \neq i} P_{=?}[\phi_{opt}(C_j)]}$$

which indicates its capability to discriminate between time series of cluster i from time series of the most similar cluster j ≠ i.

Results

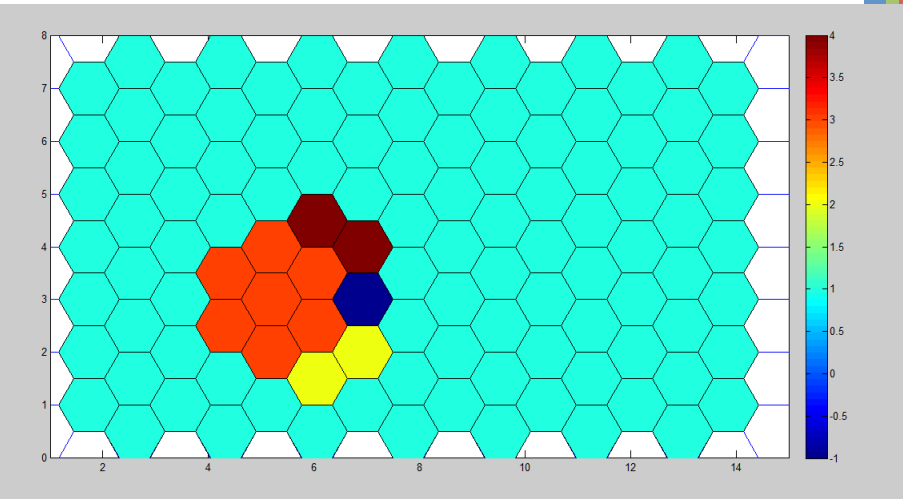
Best clustering result (using DBScan)

Wild Type Tissue



- All the cells have the same behaviour
- The borders are effect of a biased model

Mutated Tissue



- The mutated clone is clearly visible
- Nearby “wild type” cells are INFLUENCED by the mutated clone

DISCOVERED PROPERTIES

PLTLc EXAMPLE:

Behaviour in the INFLUENCED CELLS

$$P_{=?}[d[FFD] > 0\ U(Time \geq 30 \wedge Time \leq 31 \wedge d[FFD] = 0\ \wedge G(d[FFD] = 0)))]$$

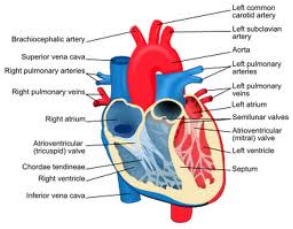
“The concentration of FFD increases from time zero, reaches its peak
between time 30 and 31, and then becomes steady till the end”.

Q. Gao, D. Gilbert, M. Heiner, F. Liu, D. Maccagnola and D. Tree, (2013). Multiscale Modelling and Analysis of Planar Cell Polarity in the Drosophila Wing, IEEE/ACM Transactions on Computational Biology and Bioinformatics, 10:2.

Systems biology

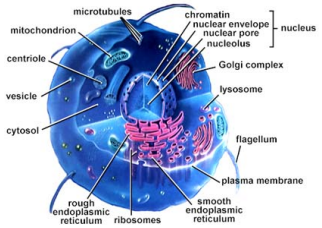
Biological systems are **multidimensional** …

Organism



Organ

Tissue

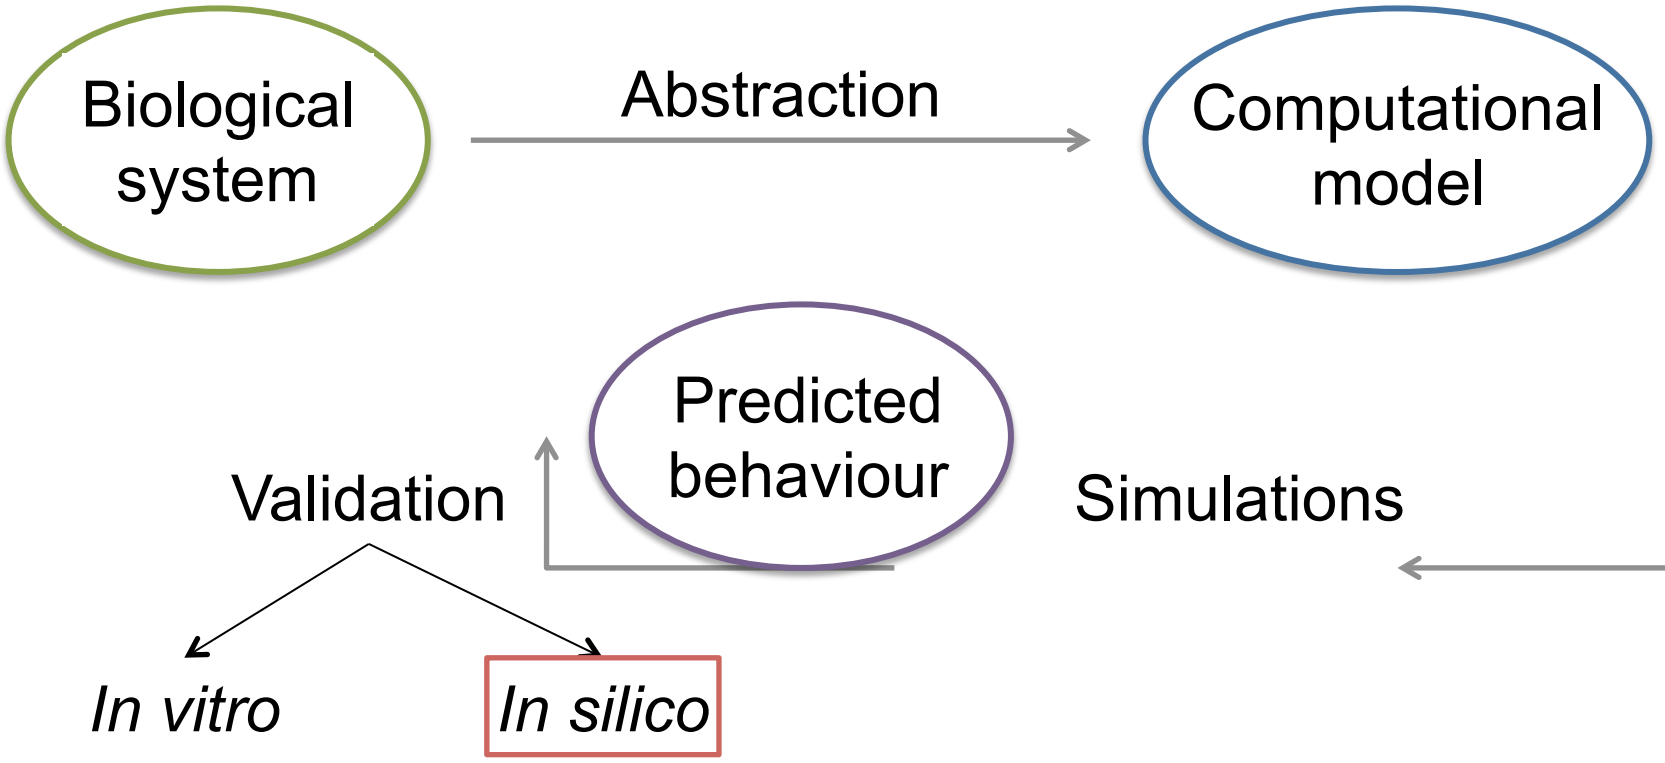


Cell

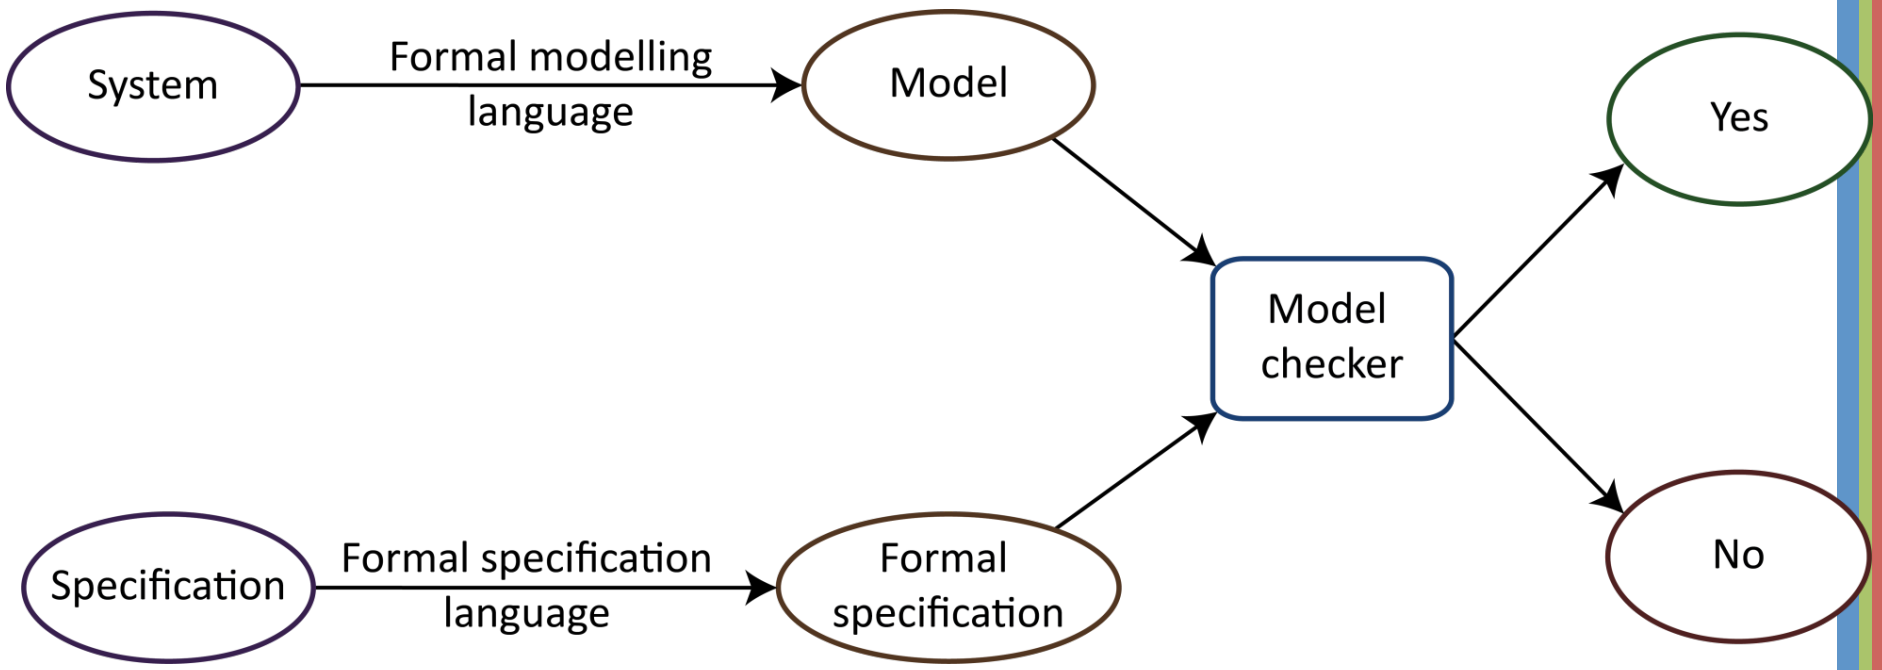
Gene

… and **multiscale**.

Computational models of biological systems

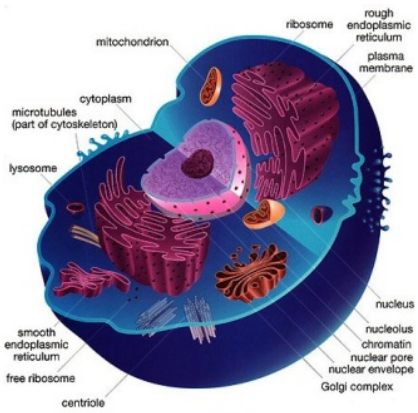


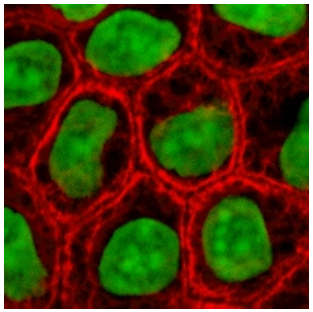
Model checking

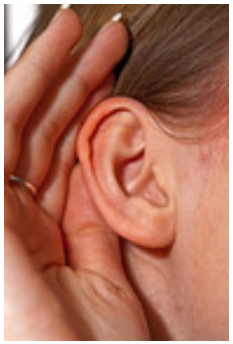


Multiscale!

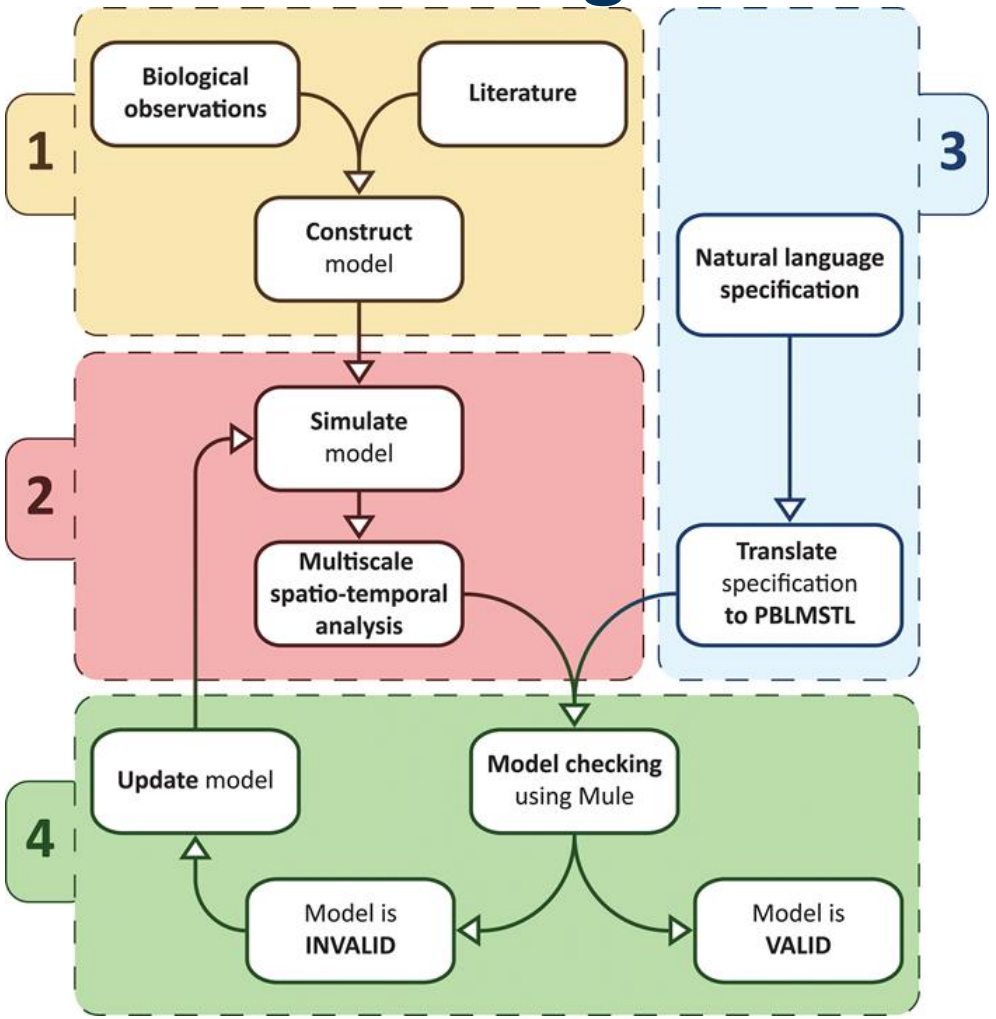
Work by Ovidiu Parvu
PhD student





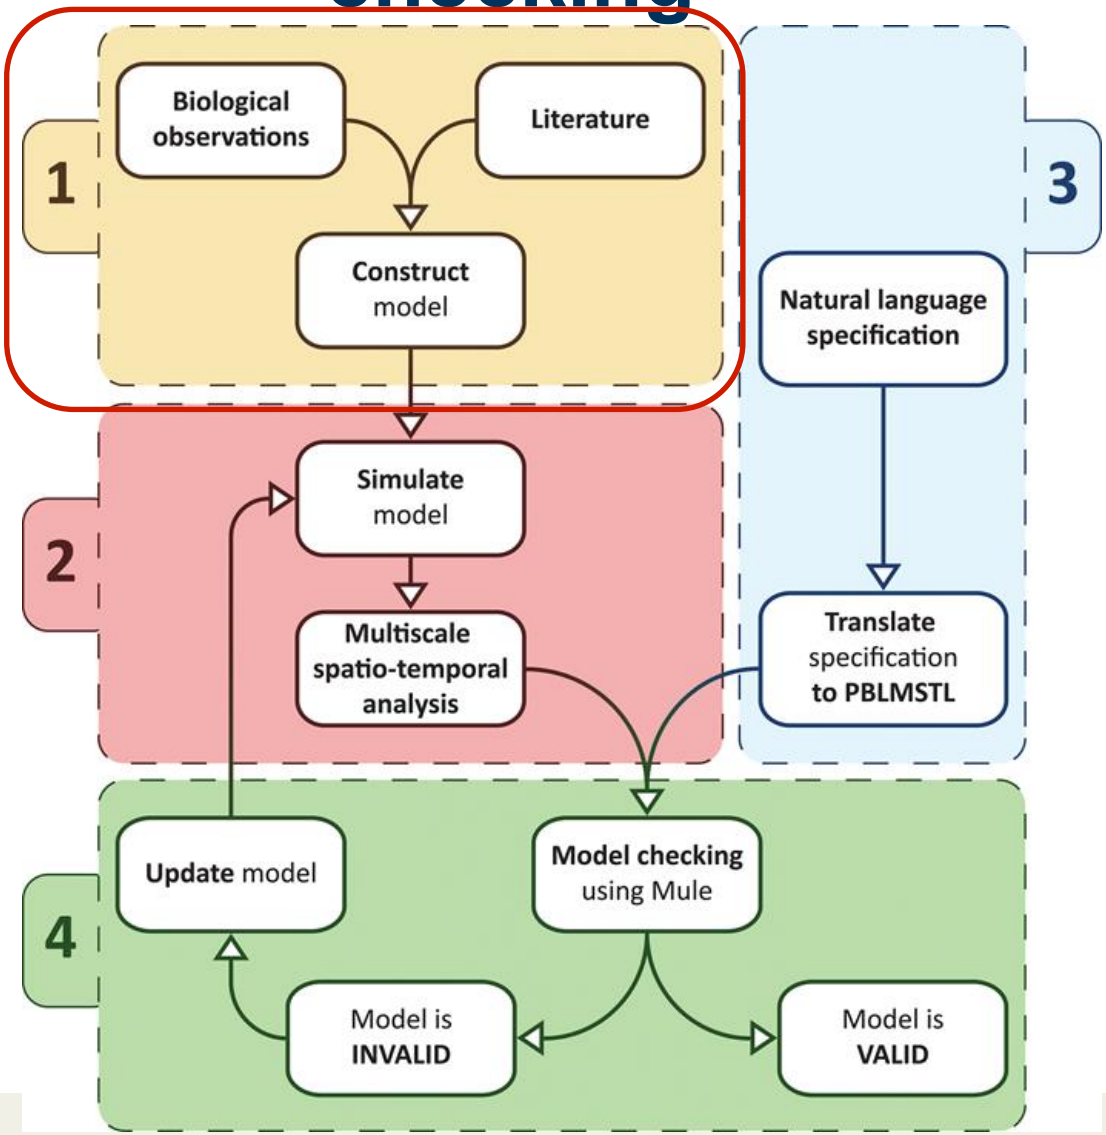


Multiscale spatio-temporal model checking



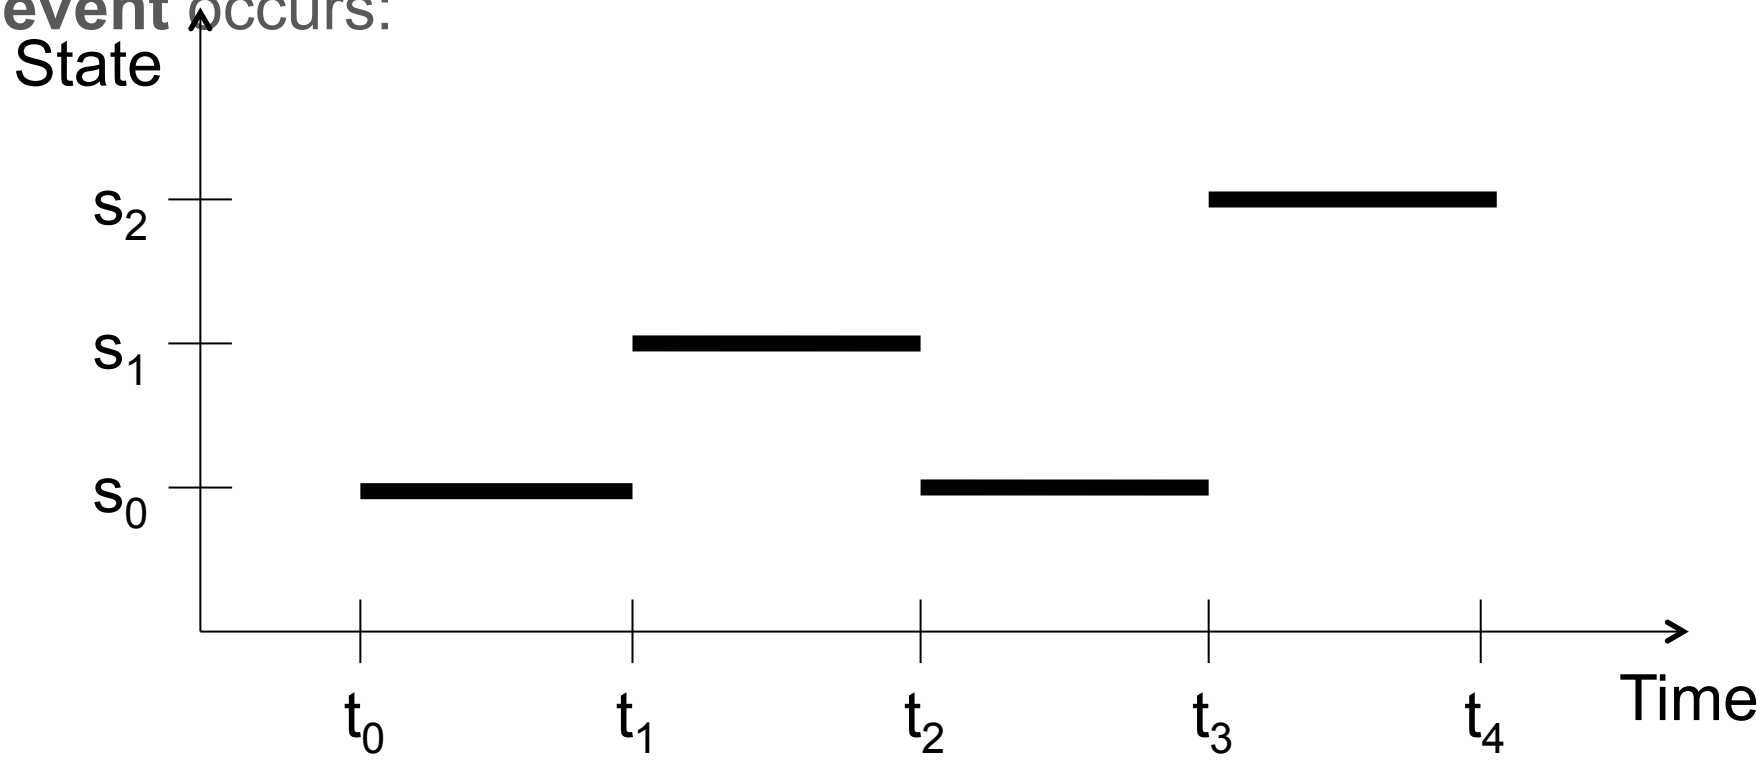
[1] O. Pârvu and D. Gilbert, "A novel method to verify multilevel computational models of biological systems using multiscale spatio-temporal meta model checking," *PLoS ONE* **(under review)**.

Multiscale spatio-temporal model checking



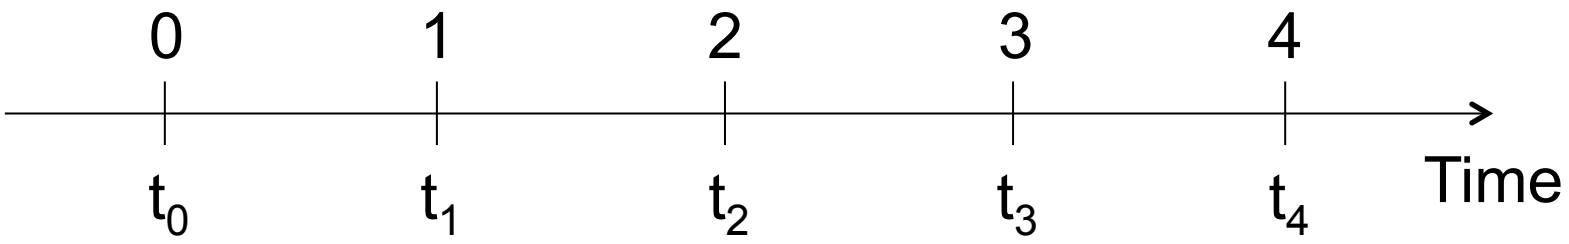
Assumption: stochastic discrete-event systems

The modelled biological systems are assumed to be **stochastic** and transition between states only when an **event** occurs:

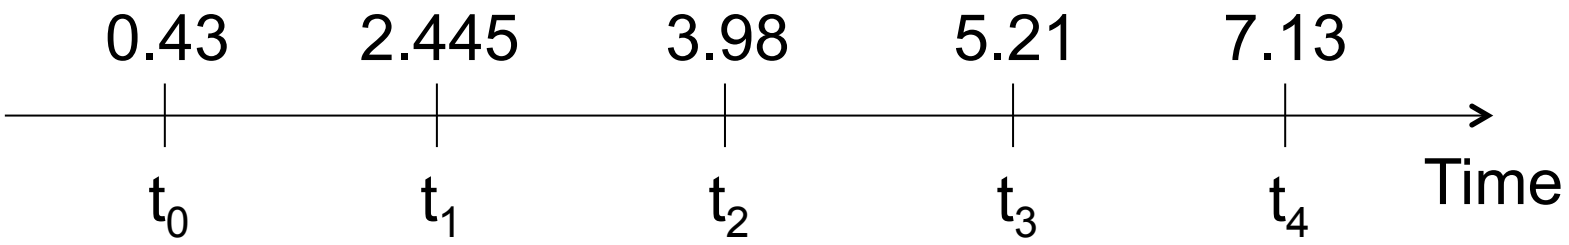


Assumption: Discrete or continuous time

Time is represented in either a **discrete**:

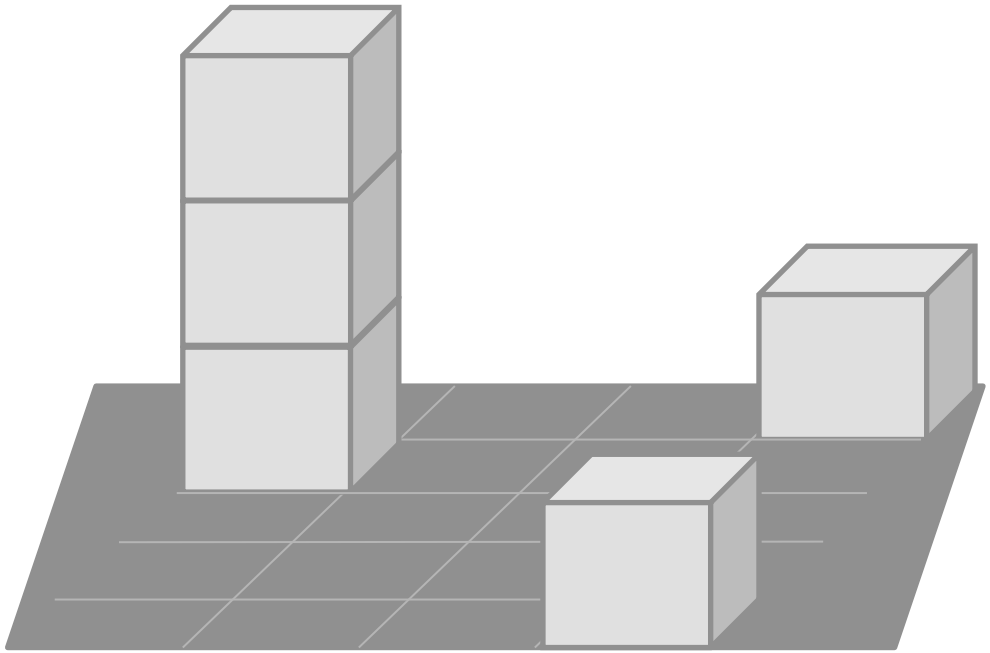


or **continuous** manner:



Assumption:
Pseudo-3D discretised space

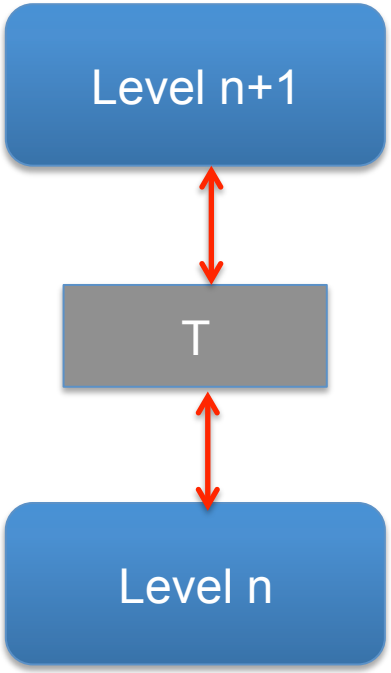
Discretised spatial domain is represented in **pseudo-3D** dimensions i.e. 2D space in which **pile up** is allowed.

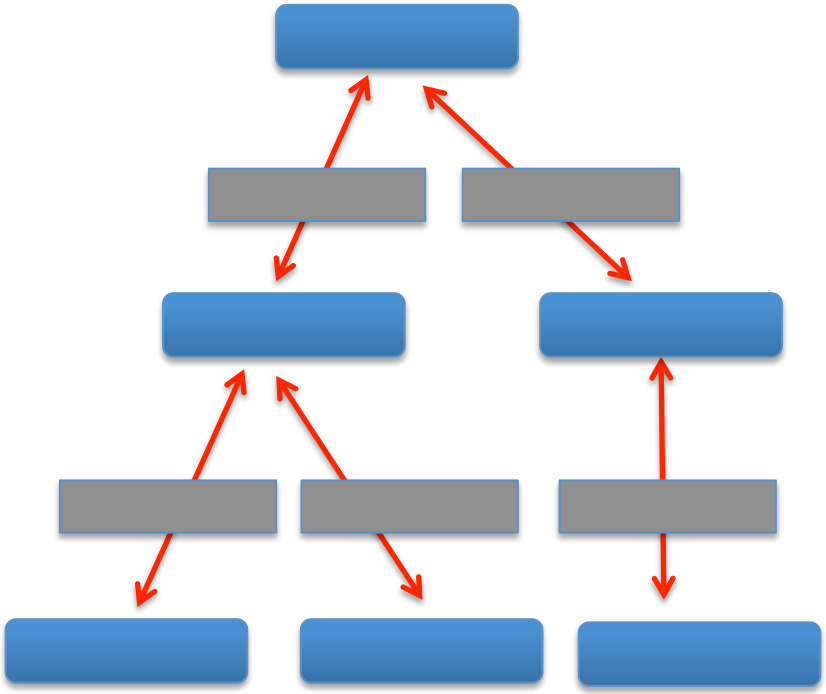


Concepts

- **Multiple scales**: time; space (1, 2, 3D),
- **Development**
- **Hierarchy of organisation** in organisms
- **Levels in hierarchy**: inherently associated with time & space scales?
- *Atomic, molecular, sub/intracellular (organelles, compartments), cellular, intracellular, tissues, organs*,…
- **Hierarchy – tree** (partially ordered upper semi-lattice).

Levels, Hierarchy





General approaches to multiscale modelling

- Models may be at many **different scales in time and space** – these **scales may be fixed or change** through the evolution of the model.

- **Operator splitting** is a powerful approach – splitting the problem into sub-problems and applying them composition-wise in some manner. This splitting generates a splitting error that depends on the stepsize.

- But **how do we split?** How do we control the splitting errors? How do we know that we converge to the right solution? Can we have a general formalism for these ideas? Can we inform different scientific communities so that both benefit.

- **Can we do parameter estimation on the fly** as we evolve from subproblem to subproblem?

Calibrating multi-scale spatial models to observations

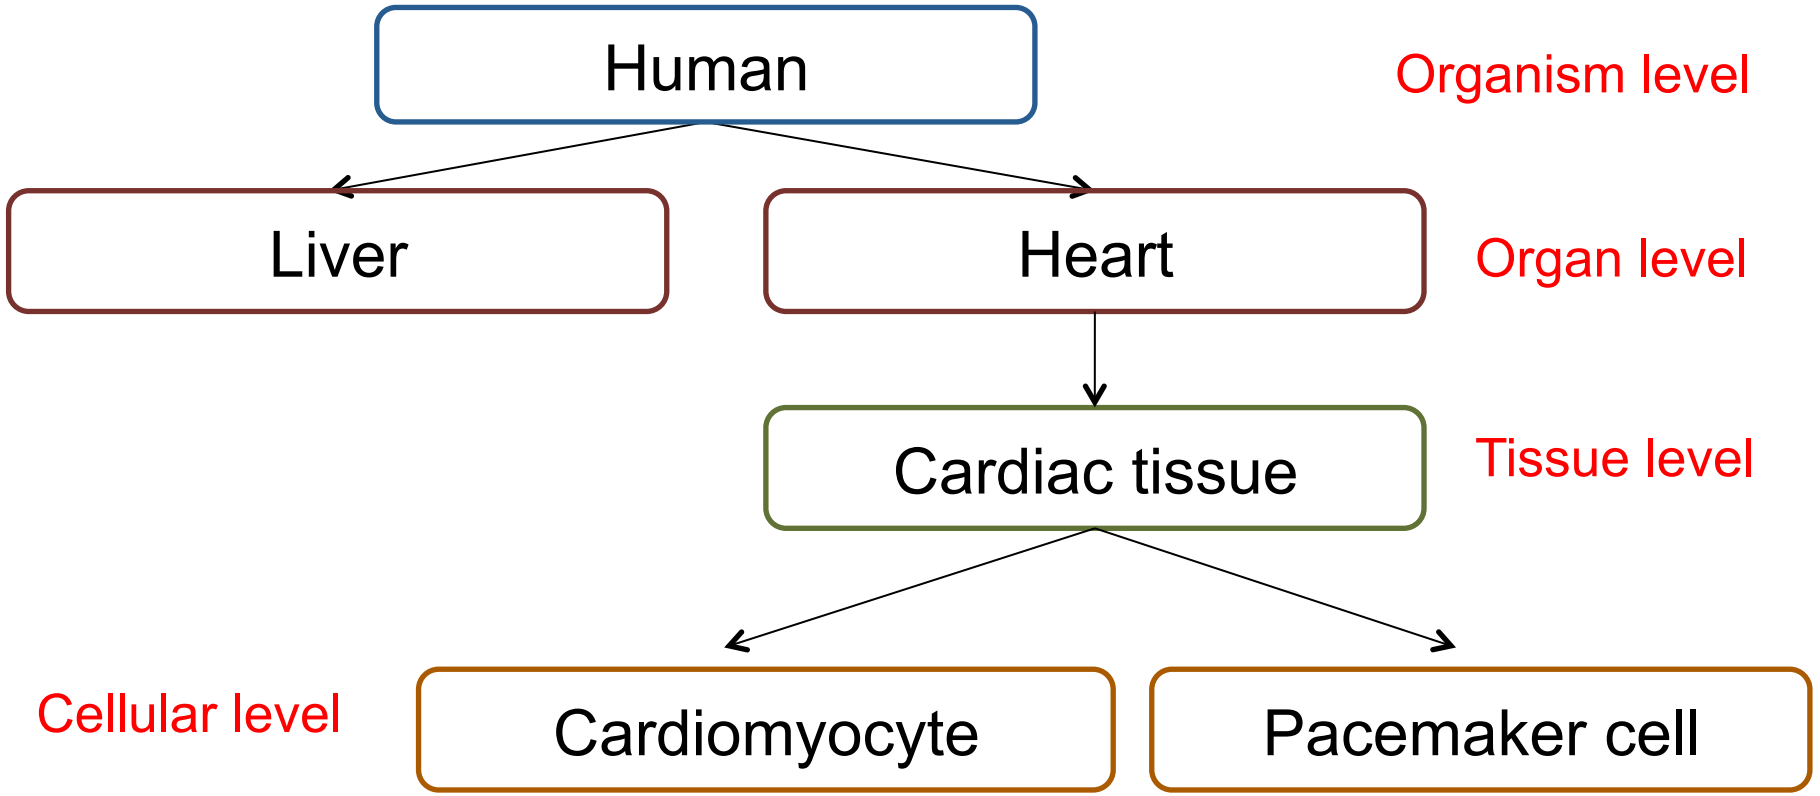
- **Calibrating spatio-temporal multi scale models to observation is hard.** Compared to non-spatial/ single level models, simulation times of spatially extended models are considerably longer, precluding exhaustive parameter sweeps and making local search algorithms impractical.

- **Spatial heterogeneity**: physical parameters of a PDE system are location dependent, so that the parameter estimation much harder function estimation problem.

- Both these **problems are compounded in the case of multi-scale system**: not only the calibration problem has to be solved for each levels, but generally the coupling between the different levels (transfer function) is also unknown.

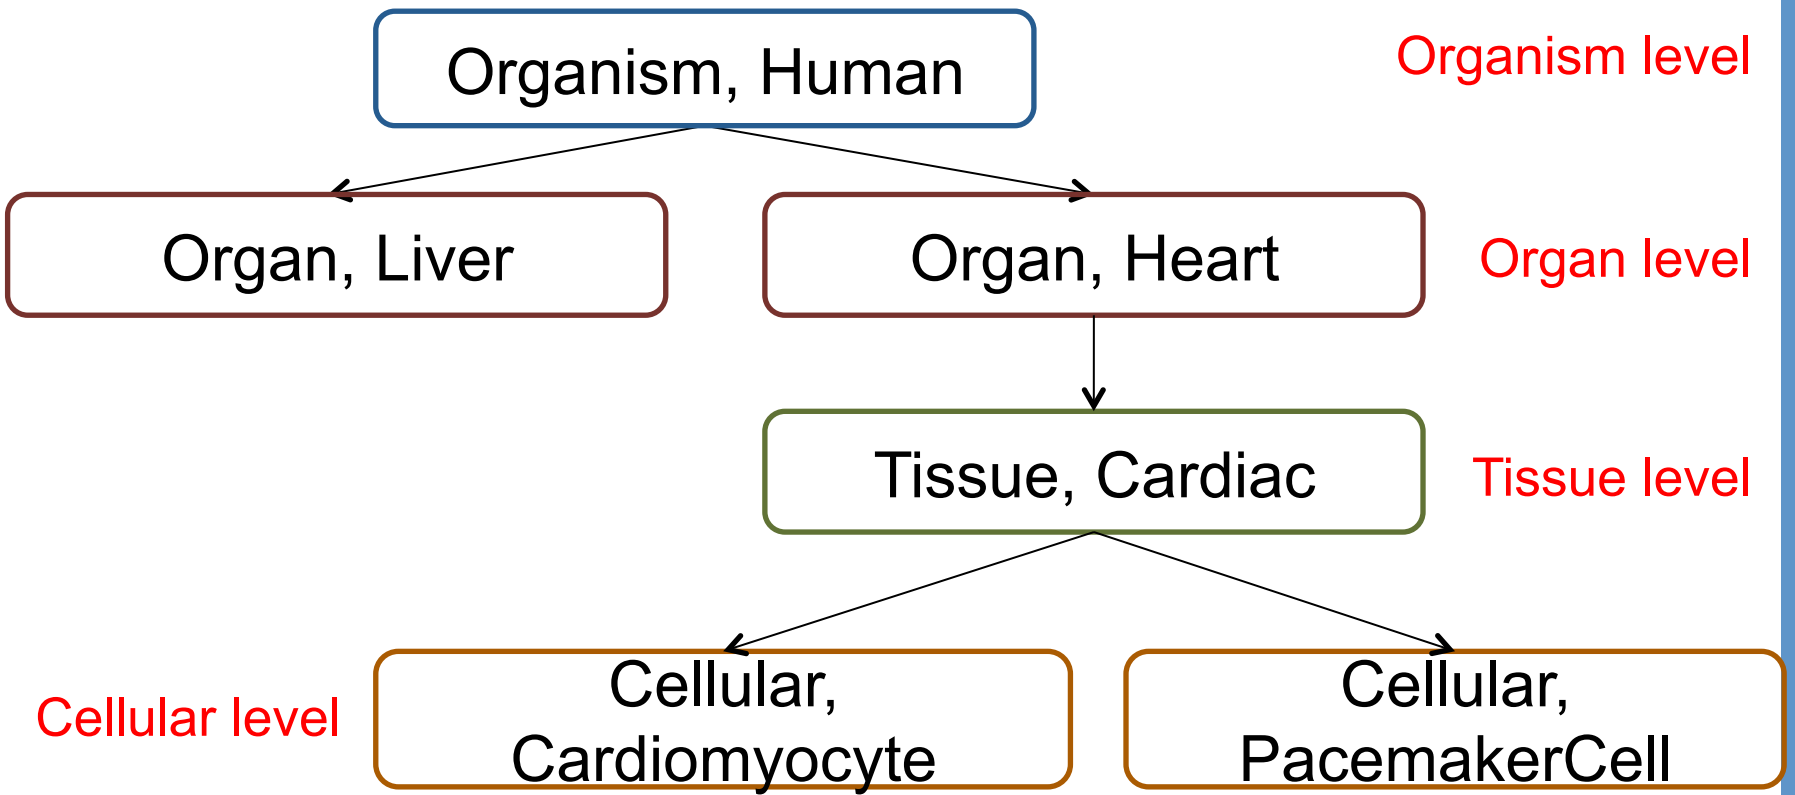
Assumption: Multiscale representation

Biological systems which are **multilevel** (i.e. span multiple levels of organization) are assumed to be inherently **multiscale** (i.e. span multiple spatio-temporal scales)



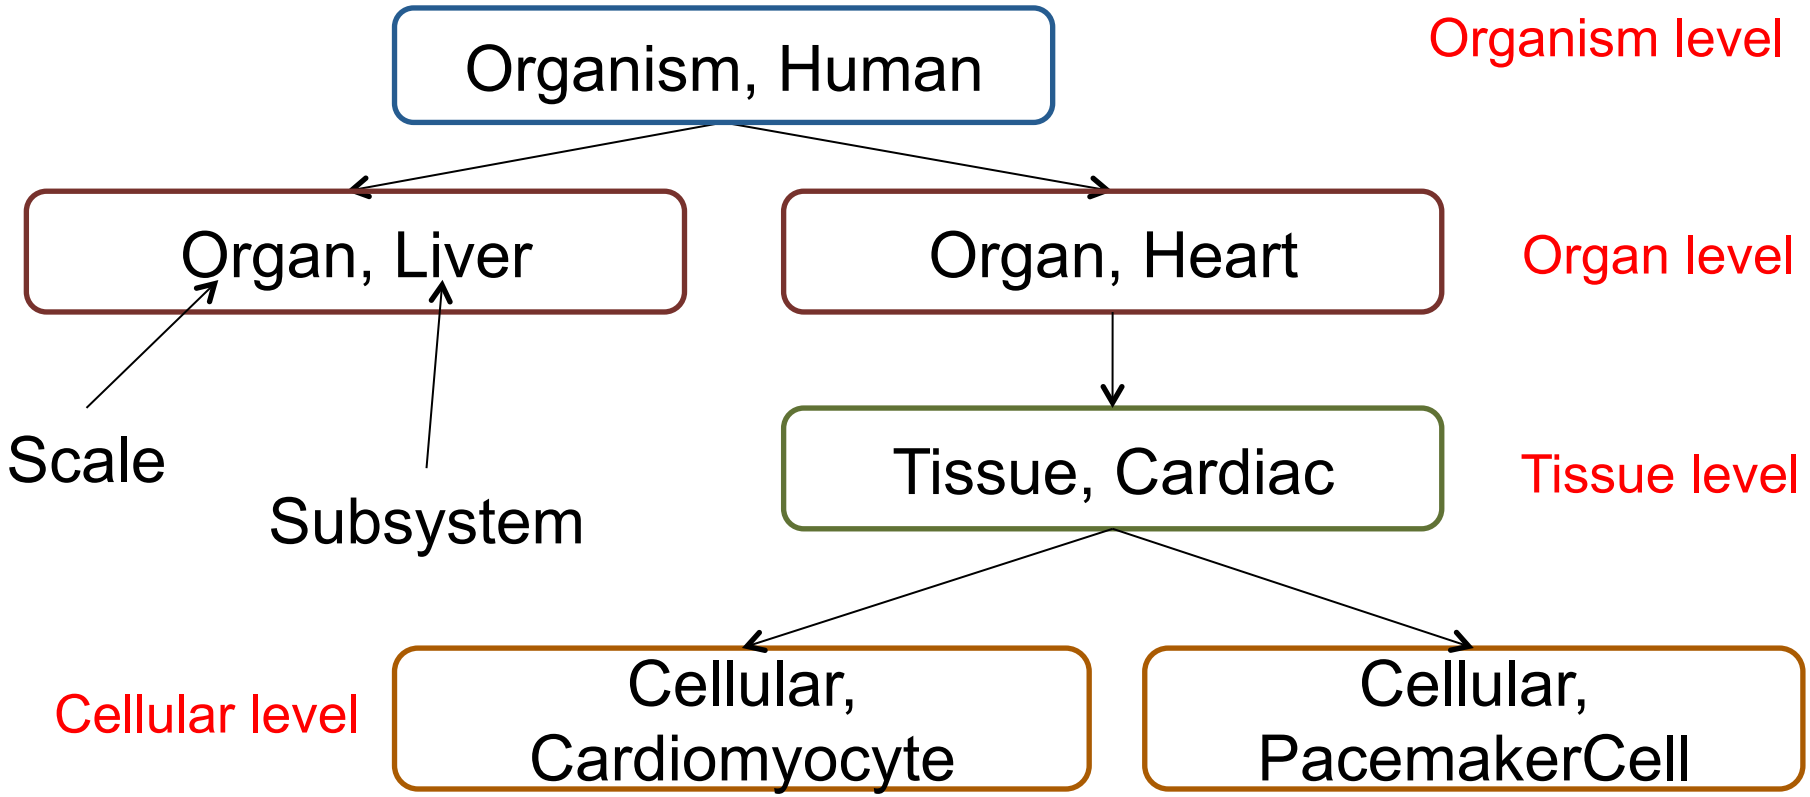
Assumption: Multiscale representation

The multiscale structure of biological systems is encoded as a rooted directed tree $MA = (V_{MA}, E_{MA})$ called the **multiscale architecture** graph



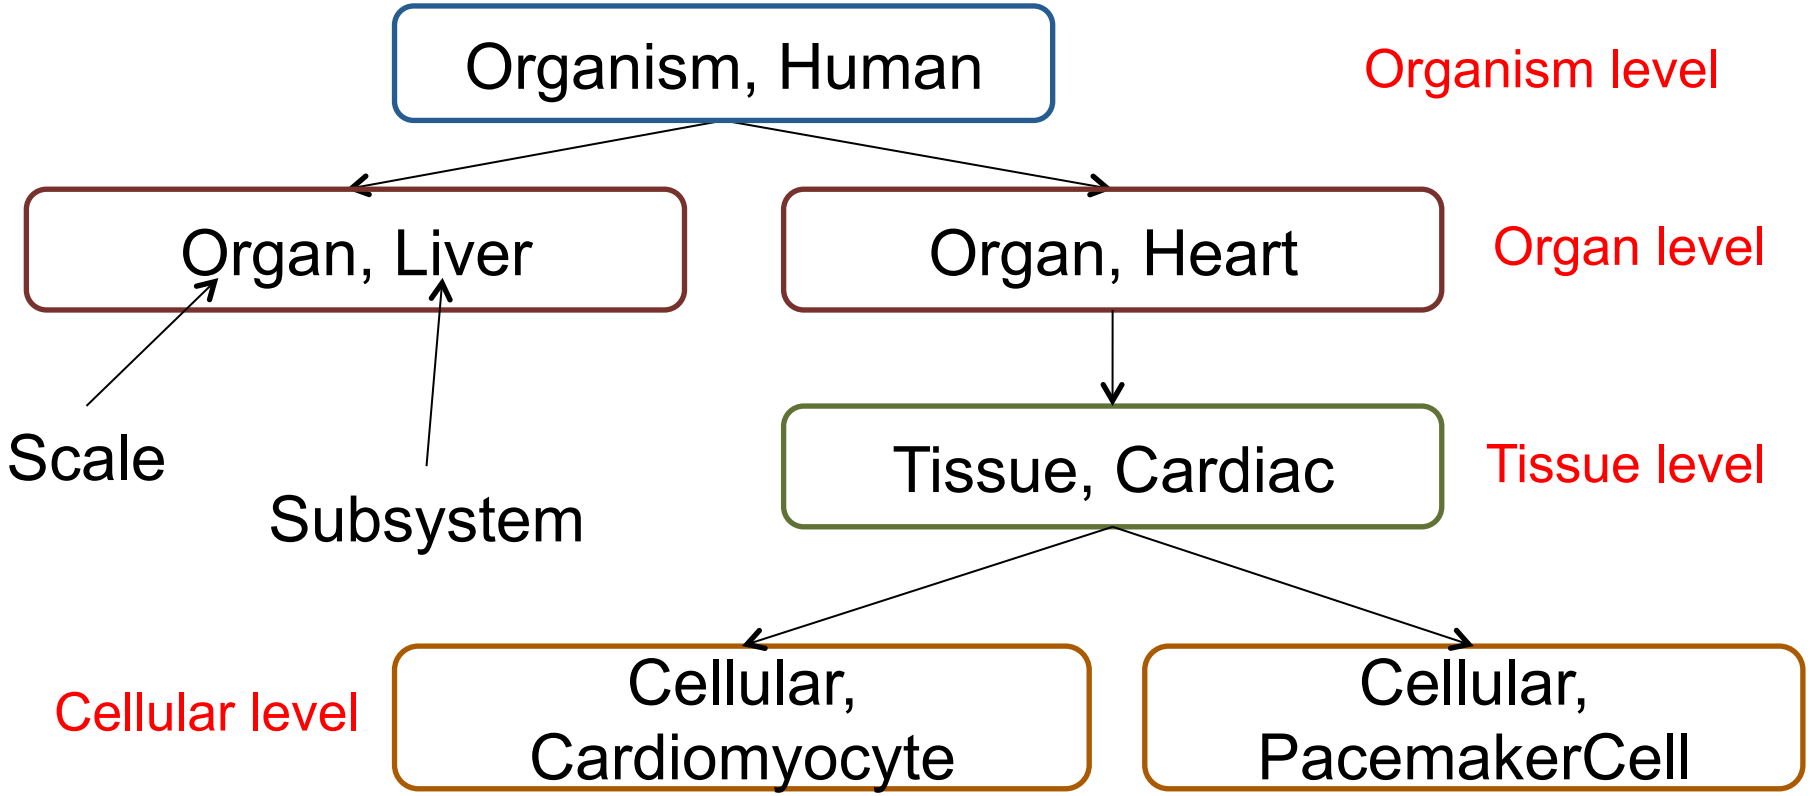
Assumption: Multiscale representation

Each vertex in the set V_{MA} is encoded as a tuple **(Scale, Subsystem)** and relations between scales and subsystems are encoded as edges in the set E_{MA}

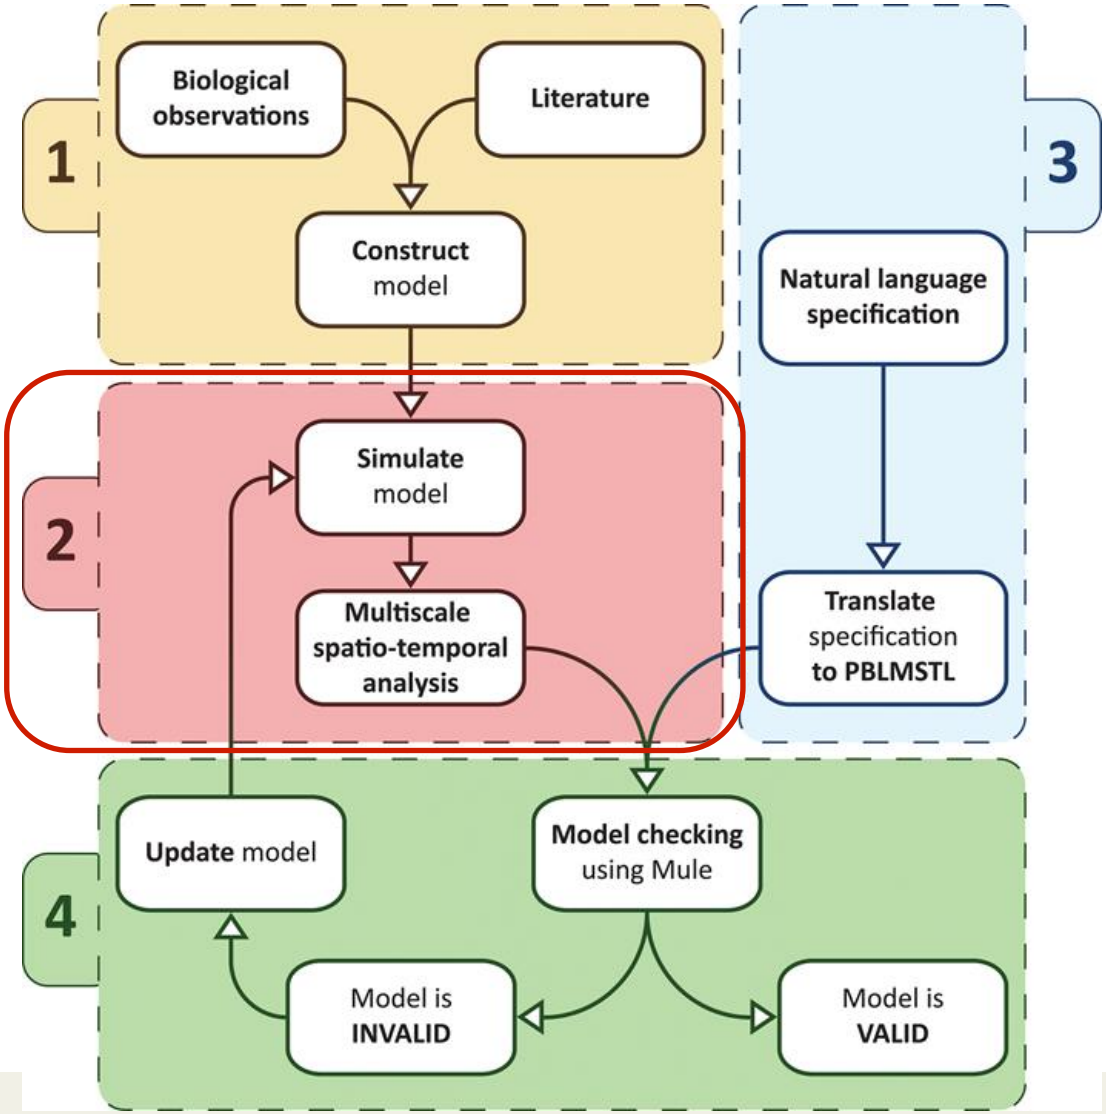


Assumption: Multiscale representation

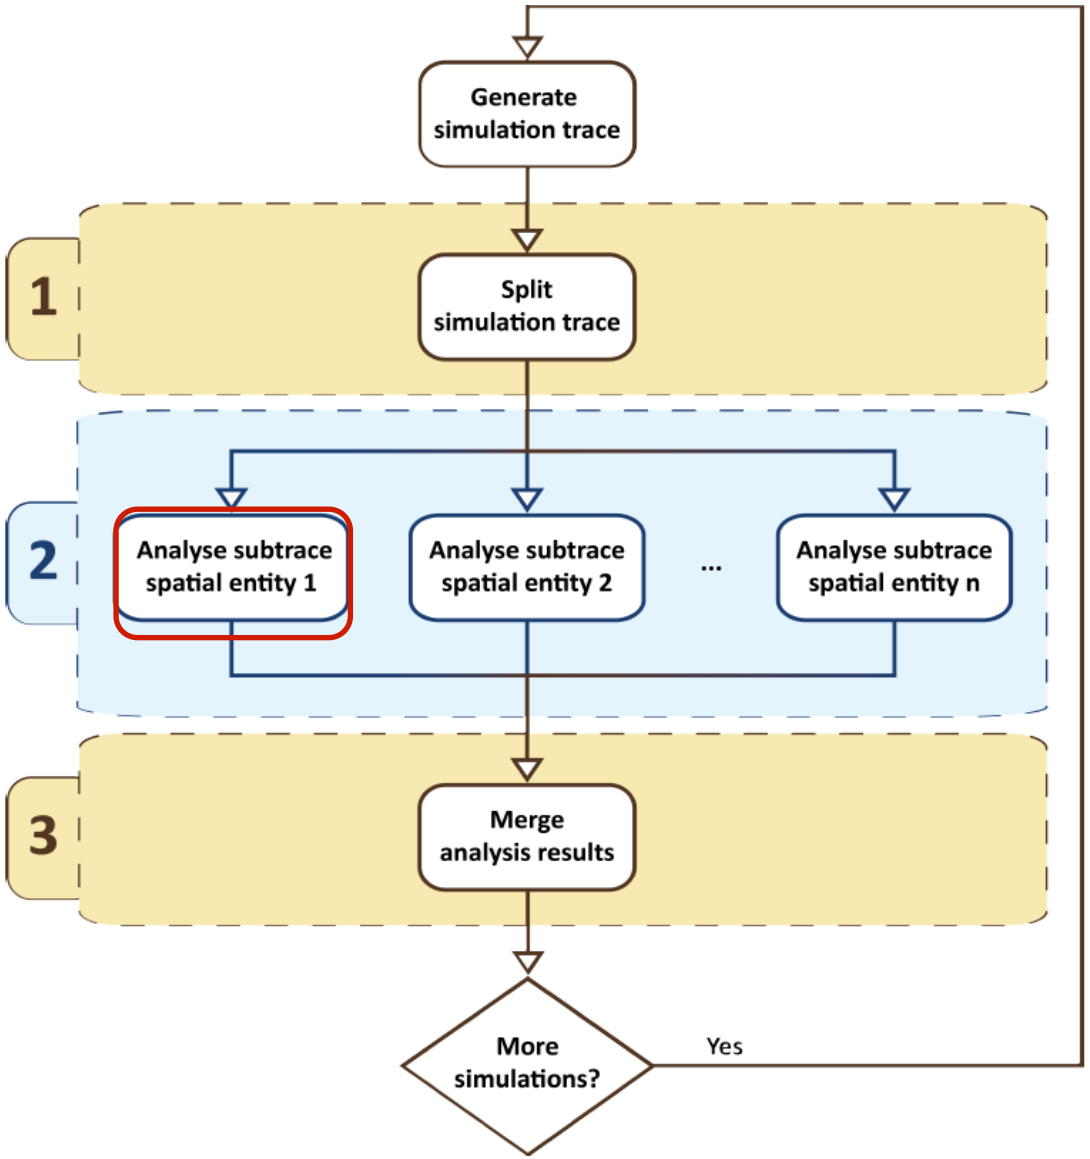
A strict **partial order <** can be defined over the set of vertices
(e.g. (Tissue, Cardiac) < (Organism, Human))



Multiscale spatio-temporal model checking

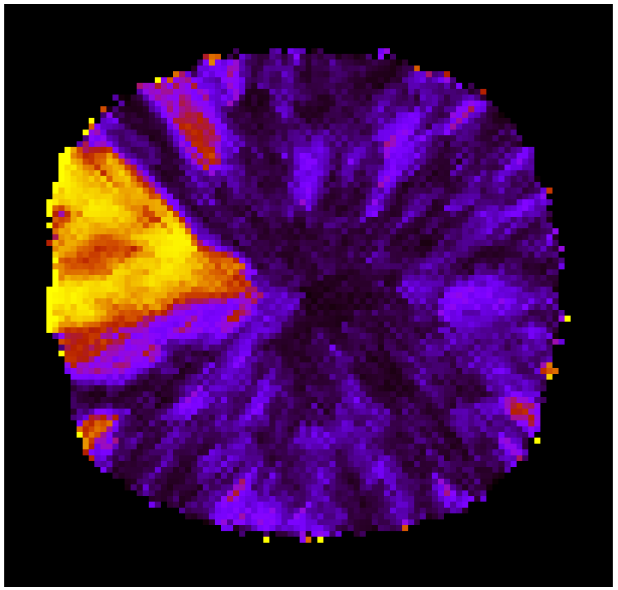


Multiscale spatio-temporal analysis

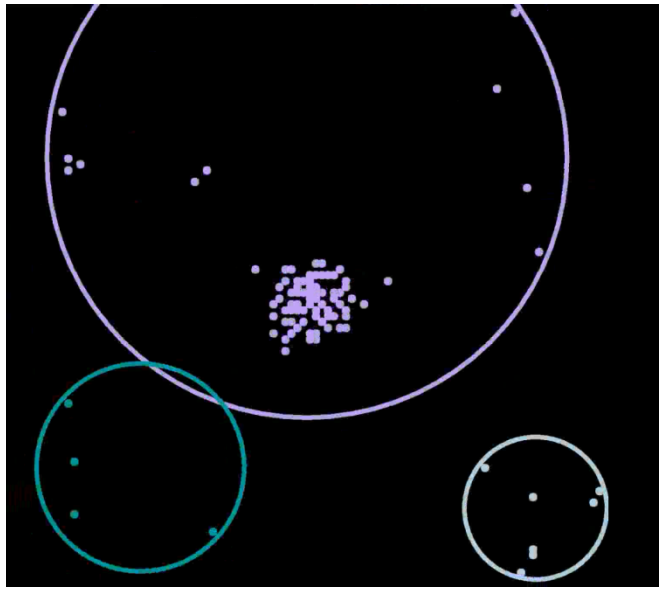


Spatio-temporal detection and analysis

Spatio-temporal detection and analysis modules enable detecting **regions** and **clusters**



Region
(e.g. bacterial colony growth)



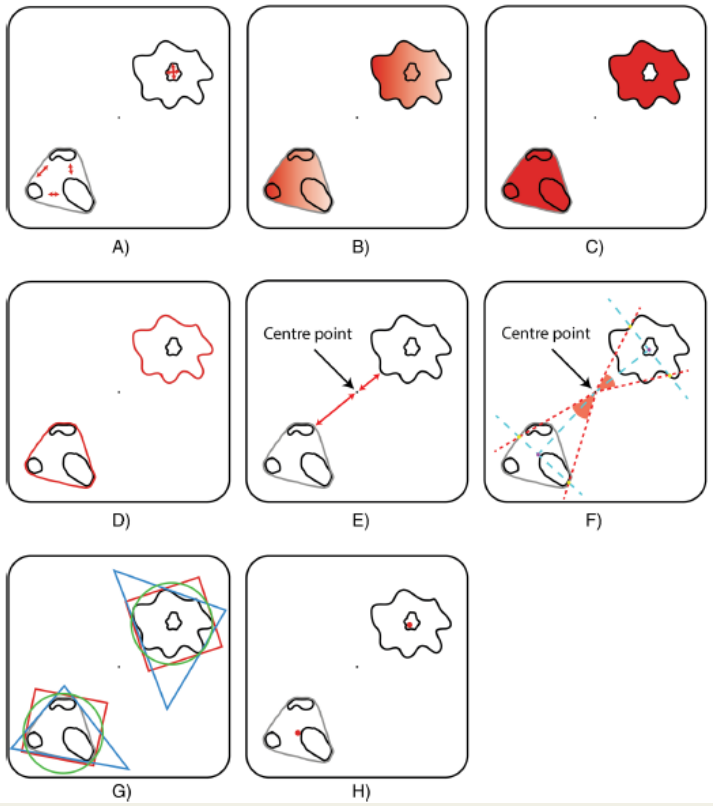
Cluster
(e.g. chemotaxis)

[2] O. Pârvu and D. Gilbert, “Automatic validation of computational models using pseudo-3D spatio-temporal model checking,” *BMC Systems Biology*, vol. 8, no. 1, p. 124, Dec. 2014

Spatio-temporal detection and analysis

For each spatial entity detected the following set of **properties** is computed:

- *Clusteredness*
- *Density*
- *Area*
- *Perimeter*
- *Distance from origin*
- *Angle*
- *Triangular, rectangular and circular measure*
- *Centroid*



Multiscale model simulation results

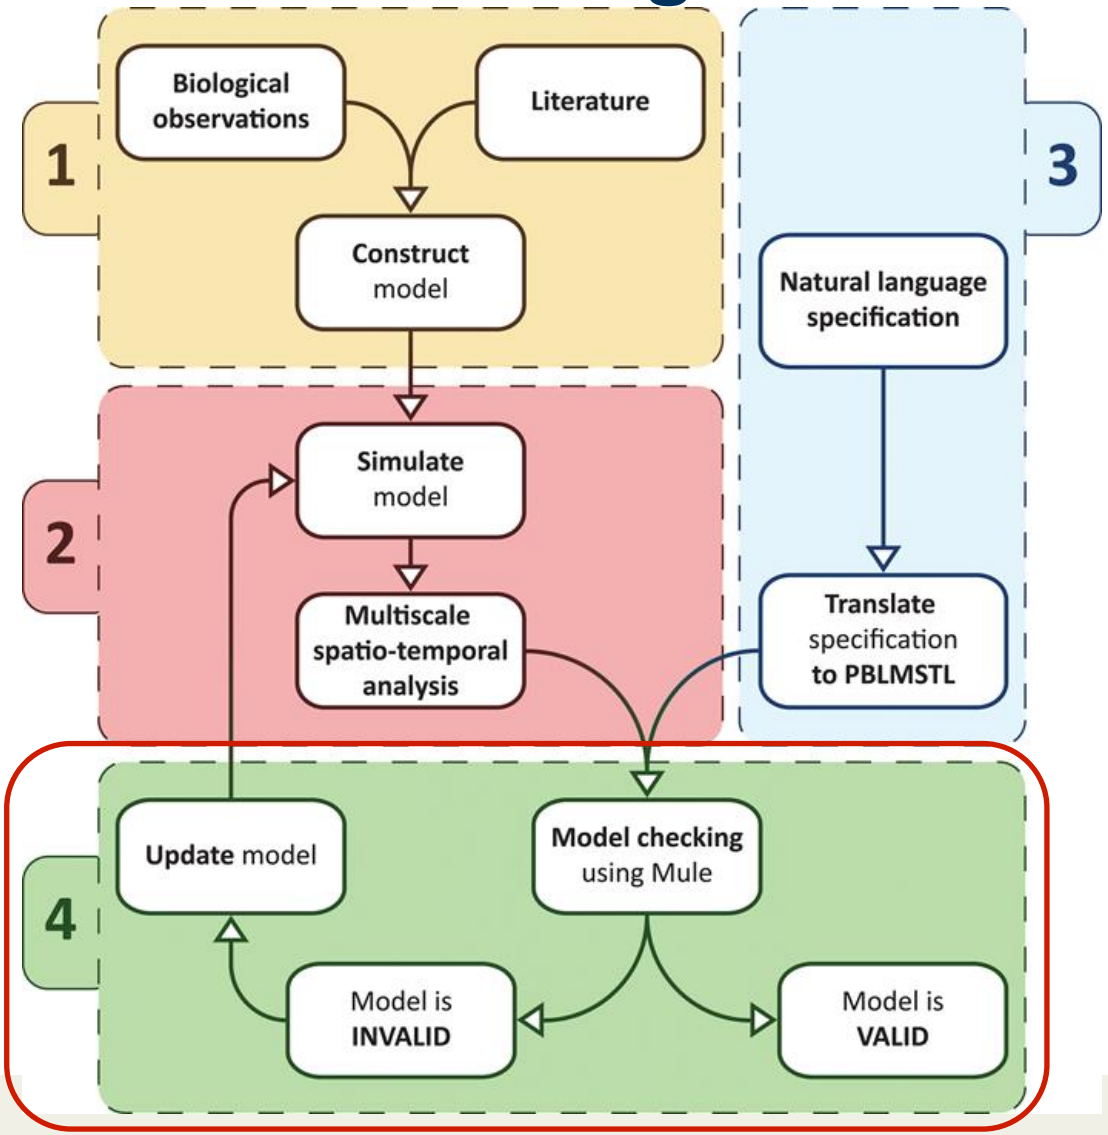
Multiscale spatio-temporal model checking



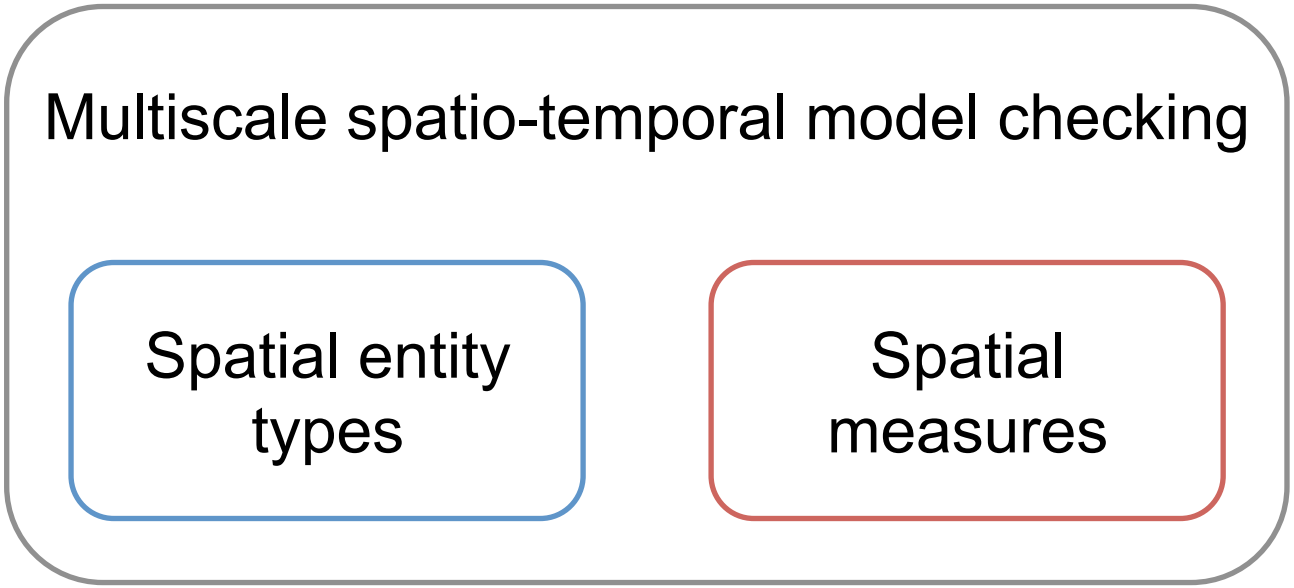
Multiscale spatio-temporal model checking

Approximate probabilistic model checking algorithms supported:

	Frequentist	**Bayesian**
Estimate	Based on Chernoff-Hoeffding bounds	Based on mean and variance
Hypothesis testing	Statistical, Probabilistic black-box	Statistical

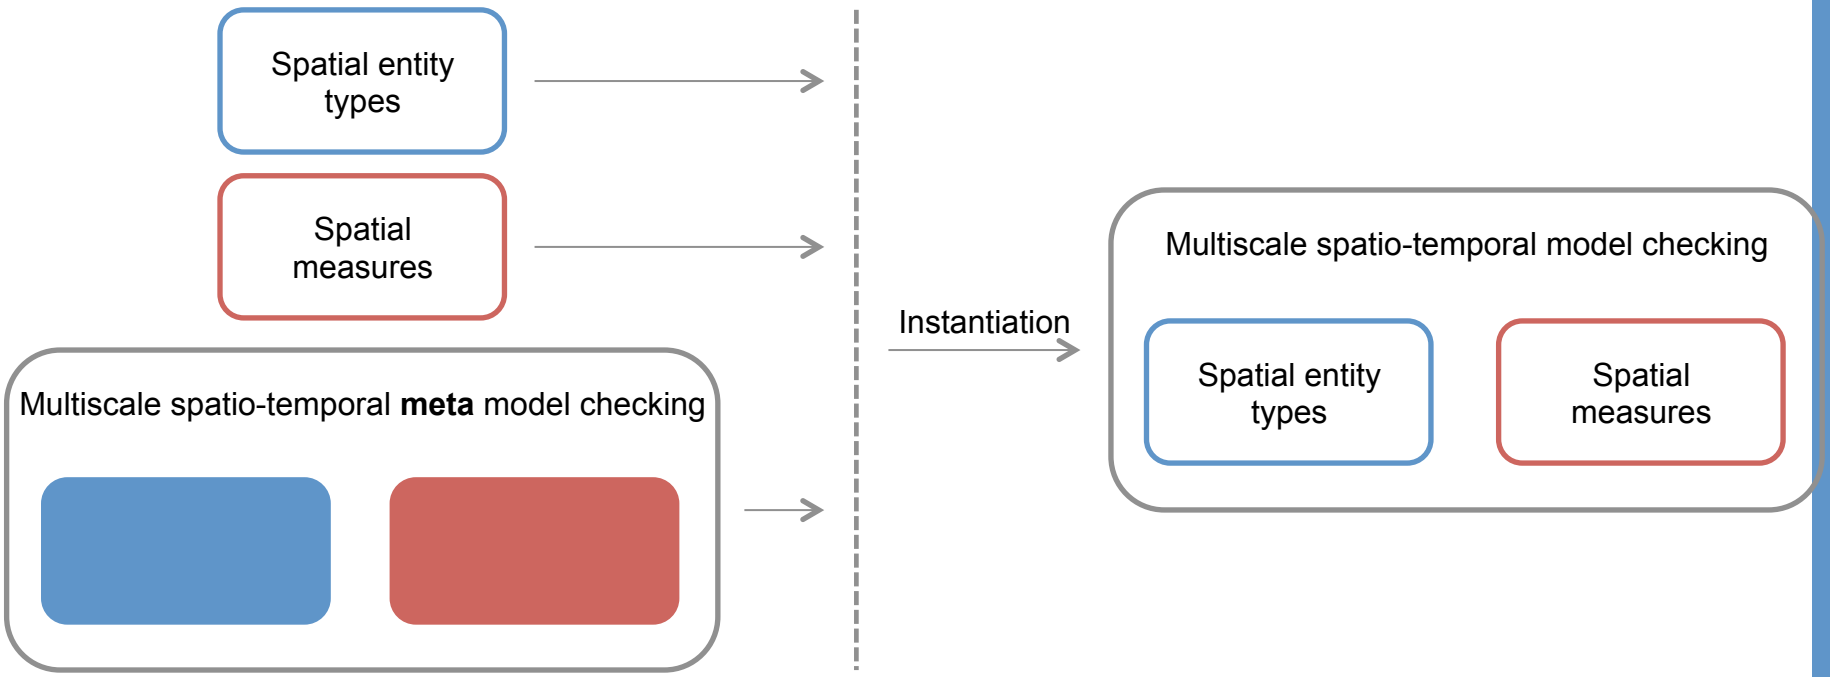
Multiscale spatio-temporal meta model checking

Multiscale spatio-temporal model checking approach as defined so far is **restricted** to particular pseudo-3D **spatial entity types** (e.g. region) and **spatial measures** (e.g. area)

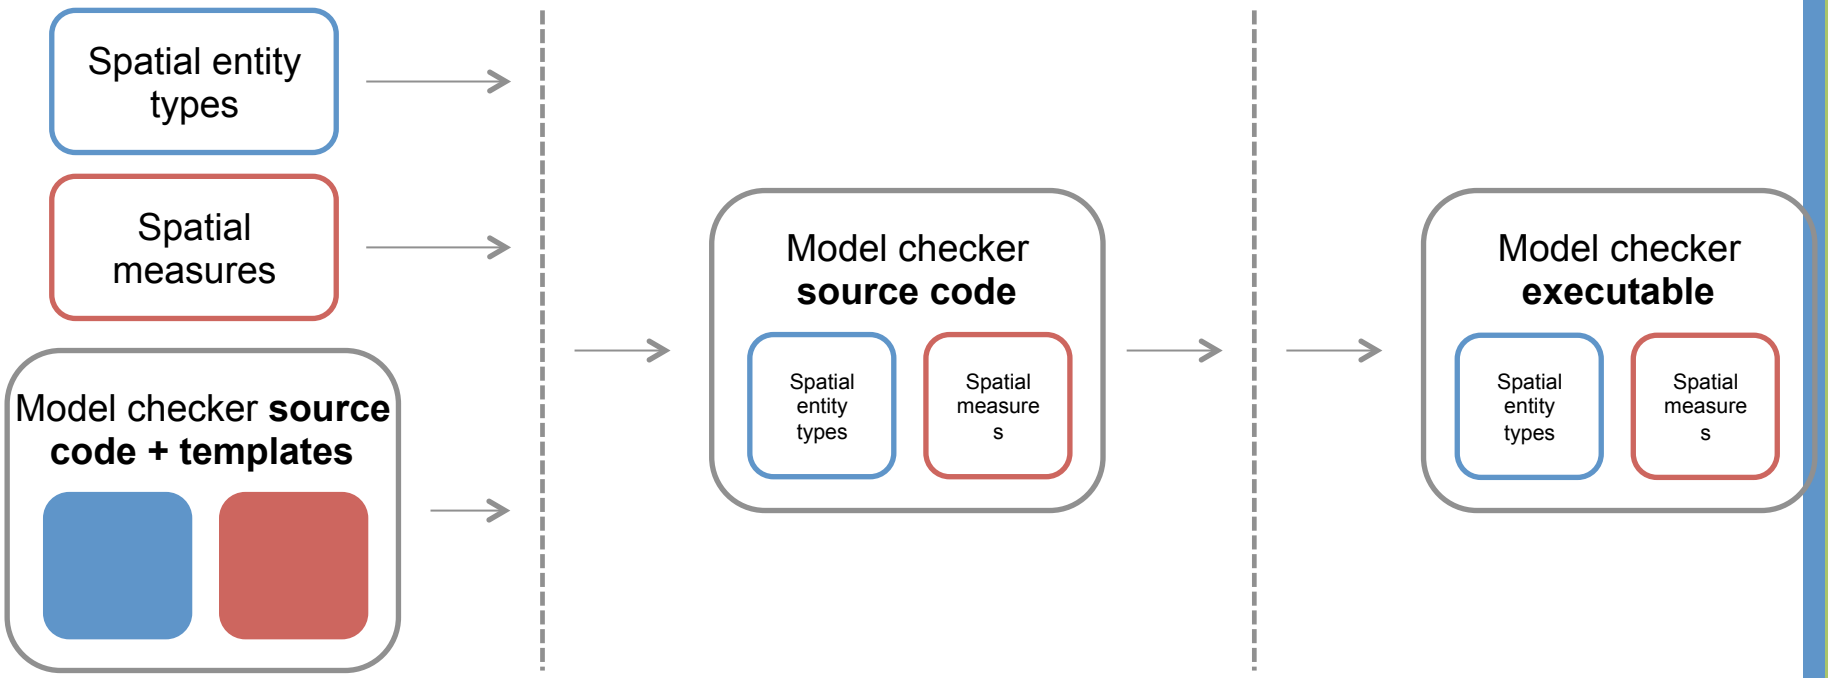


Multiscale spatio-temporal meta model checking

Multiscale spatio-temporal **meta** model checking: Define a generic **family** of multiscale spatio-temporal model checkers that can be **instantiated** for specific spatial entity types and spatial measures



Implementation



Compilation step 1
(Generate source code from templates)

Compilation step 2
(Compile source code into executable)

Multiscale spatio-temporal meta model checker

The multiscale spatio-temporal meta model checker **Mule** is made **freely available online** (binary, source code, Docker image) at http://mule.modelchecking.org

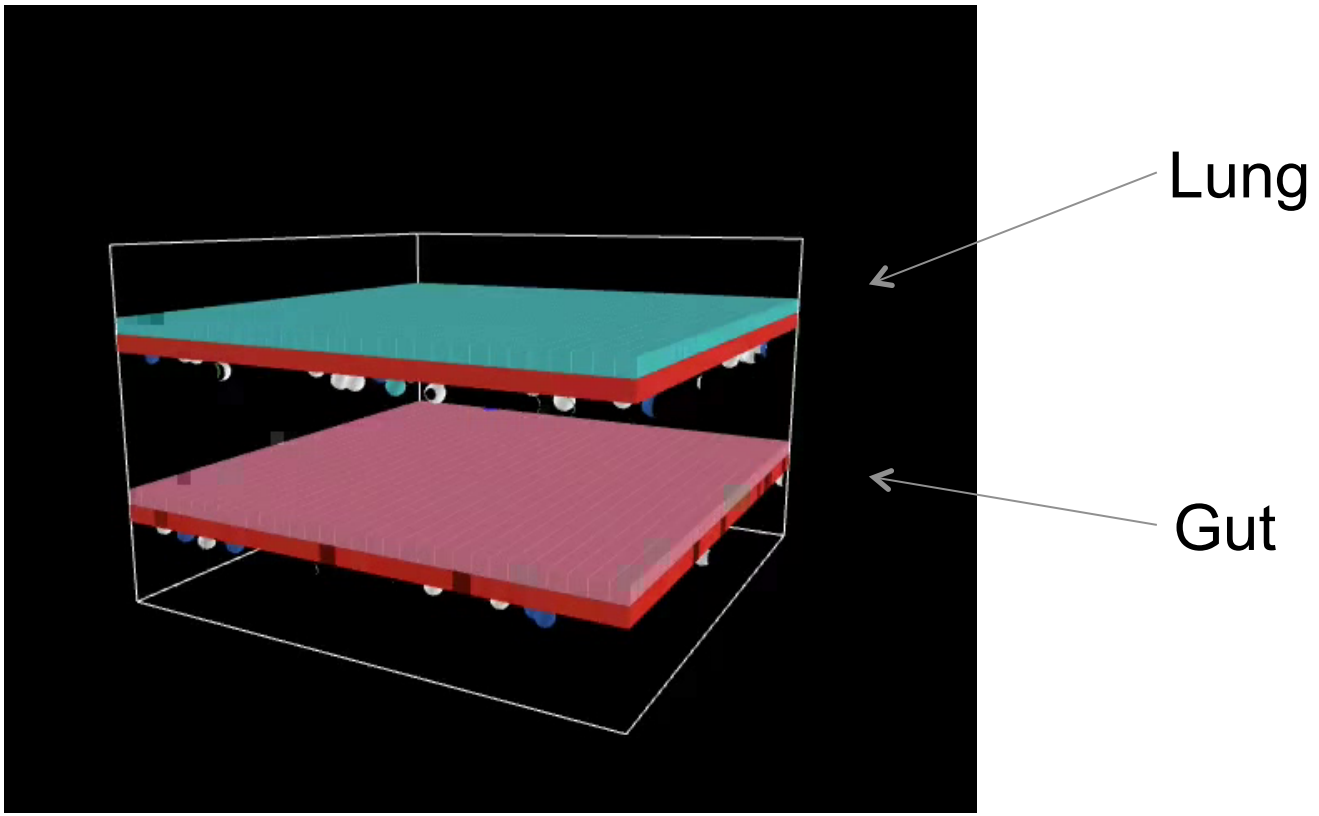
Tutorials: http://mule.modelchecking.org/tutorials

Case studies

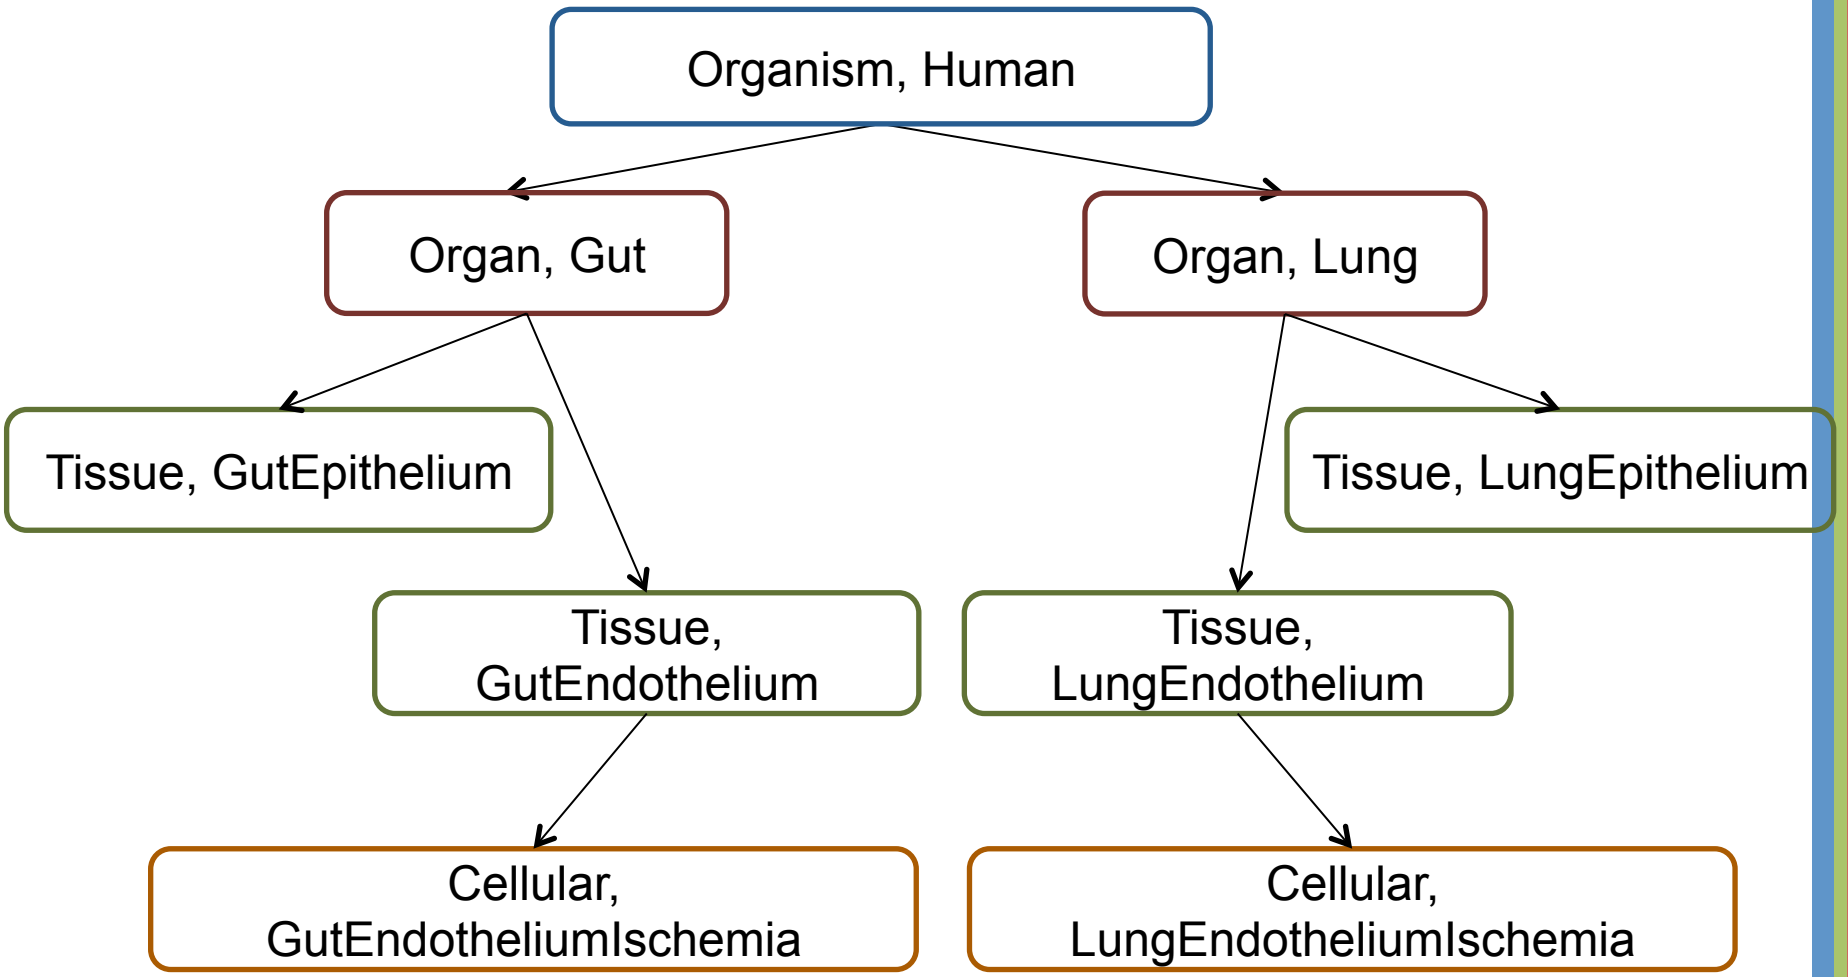
Case studies considered:

- Rat cardiovascular system dynamics [3]
- Uterine contractions of labour [4]
- *Xenopus laevis* oocytes cell cycle [5, 6]
- Acute inflammation of gut and lung [7].

Case study: Acute inflammation of gut and lung



Case study: Acute inflammation of gut and lung



Case study: Acute inflammation of gut and lung

Formal specification – statement 1:

The probability is greater than 0.9 that if the value of cytoplasm occludin in the lung (corresponding to scale and subsystem Tissue.LungEpithelium) decreases then eventually the total area of the regions defined by ischemic endothelial lung cells (corresponding to scale and subsystem Cellular.LungEndotheliumIschemia) will increase.

```
P > 0.9 [F [1, 999] ((d({LungOccludinCytoplasm}
    (scaleAndSubsystem = Tissue.LungEpithelium)) < 0) =>
    (F [1, 999] (d(sum(area(filter(regions,
    scaleAndSubsystem =
    Cellular.LungEndotheliumIschemia)))) > 0)))]
```

Case study: Acute inflammation of gut and lung

Formal specification – statement 2:
The probability is greater than 0.9 that always if the value of the gut cell damage by-product (corresponding to scale and subsystem Tissue.GutEndothelium) increases, then eventually the value of the lung cell damage by-product (corresponding to scale and subsystem Tissue.LungEndothelium) increases.

```
P > 0.9 [G [1, 999] ((d({GutCellDamageByproduct}
    (scaleAndSubsystem = Tissue.GutEndothelium)) > 0) =>
    (F [1, 999] (d({LungCellDamageByproduct}
    (scaleAndSubsystem = Tissue.LungEndothelium)) > 0)))]
```

Case study: Acute inflammation of gut and lung

Formal specification – statement 3:
The probability is greater than 0.9 that if the value of the gut cell wall occludin (corresponding to scale and subsystem Tissue.GutEpithelium) decreases then eventually the value of the gut leak (corresponding to scale and subsystem Organ.Gut) will increase.

```
P > 0.9 [F [1, 999] ((d({GutOccludinCellwall}
    (scaleAndSubsystem = Tissue.GutEpithelium)) < 0) =>
    (F [1, 999] (d({GutLeak} (scaleAndSubsystem =
    Organ.Gut)) > 0)))]
```

Conclusions

Our multiscale spatio-temporal meta model checking approach will enable computational biologists to **efficiently construct reliable** multiscale computational models of biological systems

In the future we would like to employ the meta model checking approach for analysing **real life** data sets, and to verify computational models from **other domains of science**
